Before we take leave of this subject, it is necessary to observe, that in the bay of Panama the winds between September and March are easterly; but from March till September they blow chiefly from the S. S. W. that is, during the winter months, while the sun is far from them, the winds are off shore; and during the summer months, the land being heated to a considerable degree, they are drawn towards the shore as usual. It is remarkable, however, that this is the only part on the west of a large continent where the wind shifts regularly at different seasons; which seems to be occasioned by the great height of the isthmus of Darien, and the Terra Firma to the east of it, and the nearness of these to the sea, in comparison of the mountains near Benin on the similarly situated coast of Africa; which is greatly assisted by the deepness of the bay, which, by bending so much to the eastward from Cape Lorenzo, is in a great measure screened from the force of the south winds, which allows the winter breeze to extend itself upon the bay with more facility. We ought here also to remark, that along the coast of Mexico, between Cape Pelanco and Guatemala, there are land winds which blow in the months of May, June, and July, called by the Spaniards *Poppagios*. They greatly resemble the Summalenta winds in the bay of Compeachy, as they blow both night and day a moderate breeze without intermission, sometimes three or four days or a week together. But as these blow from the land in summer only, whereas the Summalenta's blow only in winter, they must be occasioned by a different cause, which seems to be this: As the continent which divide the South Sea from the bay of Mexico and gulph of Honduras, is but of very small breadth, and in many places very high ground, the heat which it receives from the sun in summer is not so great as on the similar coast of Africa; and as the trade-wind coming from the great Atlantic ocean sweeps along the eastern part of the American coast from Cape St. Augustine to the bay of Honduras with very great violence at that season, the small heat of this narrow continent is not sufficient to stop it entirely during that season; so that at some times it blows for a short time quite across it, and occasions those winds called *Poppagios*.

Besides these more general winds, there are likewise some particular winds which are only felt in particular places at certain times, whose effects are so singular as to merit attention; some of which we shall here take notice of. In the gulph of Persia, particularly at Ormuz, during the months of June and July, there sometimes blows from the west, for a day or two together, a hot suffocating fiery wind, which scorches up and destroys any animal that may be exposed to it; for which reason, almost every body leave their habitations at Ormuz during these two months, and retire to the mountains near Schiras in Persia, where they enjoy a more comfortable climate. To explain the cause of which, it is necessary to observe, that along all the coasts of Asia, to the north of the Indian ocean, the diurnal sea and land breezes take place, as in every part of the torrid zone; by means of which the monsoons are not felt close in upon the shores. But as the monsoon

continues to blow regularly at a small distance from shore, so in all probability it continues its course without interruption at a small distance above the surface of the earth. Now when the monsoon is in its greatest vigour, its influence will sometimes descend even as low as the surface of the earth, and, interrupting the course of the breezes, hurry along with these warm vapours, which ought to have ascended upwards, and produced the salutary sea breeze; and as the earth is thus deprived of the refreshing influence and moisture of the sea-breeze, the air, by the strong reverberation of the sun-beams from such dry and sandy countries as Arabia, must soon be heated to an amazing degree, and produce these hot and suffocating winds. It is also remarkable, that these hot winds are more often experienced near headlands, where the sea-breezes are weakest, which seems to confirm this hypothesis.—Winds similar to these in kind, though not in degree, are felt upon the coast of Coromandel during the months of June, July, and August, while the west monsoon reigns; and on the Malabar coast they are likewise felt in the months of December and January, while the east monsoon reigns; but these are much less powerful than either of the others. As these hot winds always come from the land, they are known upon these coasts by the name of *Terren's*.

It has likewise been observed, that on the coast of Africa to the north of Cape Verde, during the months of December, January, and February, there sometimes blows, for a day or two together, an easterly wind, so very intensely cold as to be almost as destructive as the warm winds at Ormuz. We have already in some measure explained the cause of this phenomenon.—During these months, when the sun is far from them, his influence is less felt than at other seasons, and the northerly wind upon the coast is of course weakened, inso much that the cold produced by the mountains in the heart of the country being now in its greatest degree of force, bursts its usual confinement for a time, spreading to the west with great violence, and producing those uncommon effects already mentioned. Those who sail on these coasts, distinguish this particular wind by the name of *Harmattan*.

These are the principal winds, whether constant or periodical, that take place within the tropics; and thus simple are their causes.

The succession of sea and land breezes renders the torrid zone not only habitable but comfortable. Besides, as these currents of cold air, rushing from each side of the globe, and carrying along with them vast quantities of aqueous vapours which they collect from the surface of the earth in their course, meet and oppose one another at that part of the atmosphere where the influence of the sun is greatest at the time, the water is there forced from the clouds in such prodigious quantities, as to produce a diversity of seasons in the torrid zone, something similar to what is experienced in more temperate climates; with this difference, however, that whereas, in temperate climates, the warmest and most comfortable season is when the sun approaches nearest perpendicular to them, in these warmer climates the heavy rains which fall upon them at that season moderates the heat, and prevents the sun from having such an effect as at other times; so that their coldest and most inconstant weather, which they

Wind. they call *quinter*, is at that season, when, without this influence, they would be exposed to the sun's most powerful cause.

We shall only take notice of one other instance of the happy effects produced on our globe by the laws of nature with respect to winds. We have seen, that in the great Atlantic and Pacific oceans, the trade-wind blows constantly from the easterly points throughout the whole year, so that ships sail from east to west within the tropics with the utmost facility; but it is absolutely impossible in these seas to sail from west to east, as the wind would be constantly against them; so that ships bound for any port to the eastward in these regions, must stand to the north or south till they are beyond the limits of the trade-winds, where they meet with variable breezes, by the help of which they fail to the eastward. But if the same constant trade-wind had taken place in the northern part of the Indian ocean, it would have been impossible to have sailed to the eastward at all; because the continent of Asia would have prevented the ships from sailing far enough north to find the variable winds. But here, as in almost every case in which the operations of nature are concerned, we find, that what produceth the disease, at the same time furnisheth a remedy; for that very continent which would have stood in our way going northward, draws the wind towards itself at one season, which makes that course of navigation unnecessary, the shifting of the monsoons supplying a nearer and more commodious course. Thus we see, that wherever the sea is open to the south or north, near the tropics, so as that ships are at freedom to reach the variable winds, the trade-wind constantly blows in one direction; but, wherever there is any extent of continent within the verge of the torrid zone, so as that they could not be at liberty to reach the variable winds, there the course of the trade-wind is altered, being drawn towards it in summer, and from it in winter, forming that shifting wind called *monsoons*. From which we may naturally infer, that as there are no monsoons in the Pacific or Atlantic, or in the western part of the Indian ocean, to the south of the line, there are no extensive continents near the tropics in either of these places.

WIND-Flower. See ANEMONE.

WIND-Mill, a kind of mill, the internal parts of which are much the same with those of a water-mill: from which, however, it differs, in being moved by the impulse of the wind upon its sails or vanes, which are to be considered as a wheel in axes.

WIND-Gage. See Wind-GAGE.

WIND-Galls, in farricry. See there, § xxxii.

Instruments for measuring the strength, velocity, &c. of the WIND. See Wind-GAGE, ANEMOMETER, and ANEMOSCOPE.

The following ingenious method of measuring the velocity of the wind is extracted from a letter of the Rev. Mr Bryce of Kirknewton to the president of the Royal Society.

"The velocity of the wind near the earth is very unequal, upon account of the frequent interruptions it meets with from hills, trees, and houses, and even in open plains; the surface of the earth, though much smoother than it commonly is, must reflect and interrupt such a fluid as the air, and occasion great irregu-

larity in the velocity of its current: this is the reason when a feather is let fly with the wind, why it seldom, if ever, describes a straight line, but moves sometimes in a kind of spiral, now high; and then low, sometimes to the right, and then again to the left; and why two feathers let fly at once seldom, if ever, keep together, or describe similar lines.

"But at some considerable distance from the earth, the velocity of the wind seems to be regular and steady: nothing can be more uniform than the velocity of a cloud in the sky appears to be even in the greatest storm: it is like a ship carried away insensibly by a smooth and gentle current, passing over equal spaces in equal times. This suggested the thought, that the motion of a cloud, or its shadow over the surface of the earth, would be a much more proper measure of the velocity of the wind.

"In the end of March 1763, I had as favourable an opportunity of putting this method into practice as I could have wished for: the storm was exceeding high, and moved with vast velocity; the sun was bright, the sky clear, except where it was spotted with light floating clouds. I took my station in the north window of my dining room, near the clock, from which I had a free prospect of the fields: the sun was in the meridian, the wind due west intersecting his rays at right angles. I waited until the fore-part of the shadow of a cloud, that was distinct, and well defined, just touched a south and north line, which I had marked upon the ground: at that instant I began my reckoning, and followed the shadow with my eye in its progress, counting seconds all the while by the clock, until I had reckoned up 15 seconds; then I observed exactly where the fore-said edge of the shadow was.

"This experiment I repeated ten times in half an hour, and seldom found the difference of a second in the time which different clouds took to move over the same space. On the 5th of May current, I repeated the trial four different times, the sun being also near the meridian, the wind in the west, with light clouds floating in a clear sky as formerly; and found that the shadows of different clouds took some of them 44, and others 45 seconds, to pass over the same space which they had moved over in 15 seconds in the former trials.

Feet

This space measures exactly 1534 = space passed over in 15"

which multiplied by

4

gives 5536 = space passed over in 1 m.

which multiplied by

60

gives 332,160 = space passed over in 1 h.

"Which space is = 62.9 English miles per hour, the velocity of the wind in March 1763.

"One third of this (or 21 miles nearly) shows the velocity of the wind on May the 6th, when it blew a fresh gale.

"This day, May 12, there was a small westerly breeze, the velocity of which I measured upon the same line, the sun being 10 minutes past the meridian, and found that the shadow took 95 seconds to pass over the above space; which gives the velocity of the wind at the rate of 9.9 English miles per hour.

"Thus, by having several lines in different directions of a known length marked upon the ground, one may easily (and with great accuracy, I imagine) measure the velocity of the wind. If a person was provided

Wind
Window.

ded with an instrument for measuring the force of the wind, it would perhaps be worth while to observe whether, when the velocities of different winds were the same (or nearly so) the force of these winds did not vary with the seasons of the year, the points of the compass from which the wind blows, and also with the different state of the barometer and thermometer; since the momentum of the wind depends not only upon its velocity, but also upon its density."

WIND Sails, a fort of wide tube or funnel of canvas, employed to convey a stream of fresh air downward into the lower apartments of a ship.

This machine is usually extended by large hoops situated in different parts of its height. It is let down perpendicularly through the hatches, being expanded at the lower end like the base of a cone; and having its upper side open on the side which is placed to windward, so as to receive the full current of wind; which entering the cavity, fills the tube, and rushes downwards into the lower regions of the ship. There are generally three or four of these in our capital ships of war, which, together with the ventilators, contribute greatly to preserve the health of the crew.

WINDLASS, a machine used to raise huge weights withal, as guns, stones, anchors, &c.

It is very simple, consisting only of an axis or roller, supported horizontally at the two ends by two pieces of wood and a pulley: the two pieces of wood meet at top, being placed diagonally so as to prop each other; the axis or roller goes through the two pieces, and turns in them. The pulley is fastened at top where the pieces join. Lastly, there are two flaves or handpikes which go through the roller, whereby it is turned, and the rope which comes over the pulley is wound off and on the same.

WINDLASS, in a ship, is an instrument in small ships, placed upon the deck, just abaft the fore mast. It is made of a piece of timber six or eight feet square, in form of an axle-tree, whose length is placed horizontally upon two pieces of wood at the ends thereof, and upon which it is turned about by the help of handspikes put into holes made for that purpose. This instrument serves for weighing anchors, or hoisting of any weight in or out of the ship, and will purchase much more than any capstan, and that without any danger to those that heave; for if in heaving the windlasses about, any of the handspikes should happen to break, the windlasses would fall of itself.

WINDOW, an aperture or open place in the wall of a house, to let in the wind and light. See ARCHITECTURE, n° 83.

The word is Welch, *Uynt Dor*, signifying the passage for the wind. Window is yet provincially denominated *windor* in Lancashire; i. e. *wind-door*, or the passage for air, as that for people was peculiarly called the *door*.

Before the use of glass became general, which was not till towards the end of the 12th century, the windows in Britain seem generally to have been composed of paper. Properly prepared with oil, this forms no contemptible defence against the intrusions of the weather, and makes no incompetent opening for the admission of the light. It is still used by our architects for the temporary windows of unfinished houses, and not unfrequently for the regular ones of our work-

shops. But some of the principal buildings we may reasonably suppose to have been windowed in a superior manner. They could however be furnished merely with lattices of wood or sheets of linen, as these two remained the only furniture of our cathedrals nearly to the eighth century. And the lattices continued in some of the meaner towns of Lancashire to the 18th; and in many districts of Wales, and many of the adjoining parts of England, are in use even to the present moment.—These seem all to have been fixed in frames that were called *casementa*, and now therefore *casements* in Wales and Lancashire.

WINDSOR, a borough-town of Berkshire, 20 miles west of London, most remarkable for the magnificent palace or castle situated there on an eminence, which commands the adjacent country for many miles, the river Thames running at the foot of the hill. The knights of the garter are installed in the royal chapel here. It sends two members to parliament.

WINDWARD, in the sea-language, denotes any thing towards that point from whence the wind blows, in respect of a ship: thus windward-tide, is the tide which runs against the wind.

WINE, a brisk, agreeable, spirituous, and cordial liquor, drawn from vegetable bodies, and fermented.

All sorts of vegetables, fruits, seeds, roots, &c. afford wine; as grapes, currants, mulberries, alderberries, cherries, apples, pulse, beans, pease, turneps, radishes, and even grass itself. Hence under the class of wines, or vinous liquors, come not only wines absolutely so called, but also ale, cyder, &c.

Wine in France is distinguished, from the several degrees and steps of its preparation, into, 1. *Mere goutte*, mother-drop, which is the virgin wine, or that which runs of itself out at the top of the vat wherein the grapes are laid, before the vintager enters to tread or stamp the grapes. 2. *Muſt*, *ſurmuſt*, or *ſlum*, which is the wine or liquor in the vat, after the grapes have been trod or stamped. 3. *Preſſed wine*, being that squeezed with a press out of the grapes half bruised by the treading. The hulks left of the grapes are called *rope*, *mark*, or *mark*; by throwing water upon which, and pressing them afresh, they make a liquor for servants use, answerable to our cyderkin, and called *biſſon*. 4. *Sweet wine*, is that which has not yet worked nor fermented. 5. *Bouru*, that which has been prevented working by casting in cold water. 6. *Worked wine*, that which has been let work in the vat, to give it a colour. 7. *Boiled wine*, that which has had a boiling before it worked, and which by that means still retains its native sweetness. 8. *Strained wine*, that made by steeping dry grapes in water, and letting it ferment of itself. Wines are also distinguished with regard to their colour into white wine, red wine, claret wine, pale wine, rose, or black wine; and with regard to their country, or the soil that produces them, into French wines, Spanish wines, Rhenish wines, Hungarian wines, Greek wines, Canary wines, &c. and more particularly into Port wine, Madeira wine, Burgundy wine, Champain wine, Falernian wine, Tockay wine, Schiras wine, &c.

Method of Making, Fining, &c. WINE. In the southern parts of France, their way is with red wines to tread or squeeze the grapes between the hands, and to let the whole stand, juice and hulks, till the tincture be

Wind
Window.

fine. be to their liking; after which they press it. But for white wines, they press the grapes immediately; when pressed, they tun the must and stop up the vessel, only leaving the depth of a foot or more to give room for it to work. At the end of ten days they fill this space with some other proper wine, that will not provoke it to work again. This they repeat from time to time, new wine spending itself a little before it comes to perfection.

The usual method of fining down wines, so as to render them expeditiously bright, clear, and fit for use, is this: Take an ounce of isinglass, beat it into thin threads with a hammer, and dissolve it, by boiling, in a pint of water; this when cold becomes a stiff jelly. Whilk up some of this jelly into a froth with a little of the wine intended to be fined, then stir it well among the rest in the cask, and bung it down tight; by this means the wine will become bright in eight or ten days. This method, however, is found to be best suited to the white wines; for the red ones, the wine-coopers commonly use the whites of eggs beat up to a froth, and mixed in the same manner with their wines.

They fine it down also by putting the shavings of green beech into the vessel, having first taken off all the rind, and boiled them an hour in water to extract their rankness, and afterwards dried them in the sun, or in an oven. A bushel of these serve for a tun of wine; and being mashed, they serve again and again, till almost quite consumed.

For English wine, the method recommended by Mortimer, is first to gather the grapes when very dry, to pick them from the stalks, then to press them, and let the juice stand 24 hours in a vat covered. Afterwards to draw it off from the gross lees, and then put it up in a cask, and to add a pint or quart of strong red or white port to every gallon of juice, and let the whole work, bunging it up close, and letting it stand till January; then bottle it in dry weather. Bradley chooses to have the liquor when pressed, stand with the hulks and stalks in the vat, to ferment for 15 days. The method of converting white-wine into red, so much practised by the modern wine-coopers, Dr Shaw observes is this: Put four ounces of turnsole rags in to an earthen vessel, and pour upon them a pint of boiling water; cover the vessel close, and leave it to cool; strain off the liquor, which will be of a fine deep red, inclining to purple. A small portion of this colours a large quantity of wine. This tincture might be either made in brandy, or mixed with it, or else made into a syrup, with sugar, for keeping. A common way with the wine-coopers is to infuse the rags cold in wine for a night or more, and then wring them out with their hands; but the inconvenience of this method is, that it gives the wine a disagreeable taste, or what is commonly called the *taste of the rag*; whence the wines thus coloured usually pass among judges for pressed wines, which have all this taste from the canvas rags in which the lees are pressed. The way of extracting the tincture, as here directed, is not attended with this inconvenience, but it loads the wine with water; and if made into a syrup, or mixed in brandy, it would load the wine with things not wanted, since the colour alone is required. Hence the colouring of wines has always its inconveniencies. In those countries which do not produce the tinging grape, which affords a blood-red

Wine. juice, wherewith the wines of France are often stained, in defect of this, the juice of alder-berries is used, and sometimes logwood is used at Oporto.

The colour afforded by the method here proposed, gives wine the tinge of the Bourdeaux red, not the port; whence the foreign coopers are often distressed for want of a proper colouring for red wines in bad years. This might perhaps be supplied by an extract made by boiling slick-lack in water. The skins of tinging grapes might also be used, and the matter of the turnsole procured in a solid form, not imbibed in rags.

Stahl observes, that it is a common accident, and a disease in wines, to be kept too hot; which is not easy to cure when it has been of any long continuance, otherwise it may be cured by introducing a small artificial fermentation, that new ranges the parts of the wine, or rather recovers their former texture: but the actual exposing of wine to the fire, or the sun, presently disposes it to turn eager; and the making it boiling hot, is one of the quickest ways of expediting the process of making of vinegar.

On the other hand, wine kept in a cool vault, and well secured from the external air, will preserve its texture entire in all the constituent parts, and sufficiently strong for many years, as appears not only from old wines, but other foreign fermented liquors, particularly those of China, prepared from a decoction of rice; which being well closed down in a vessel, and buried deep under ground, will continue for a long series of years rich, generous, and good, as the histories of that country universally agree in assuring us.

The most general remedy hitherto known for all the diseases of wines, is a prudent use of tartarized spirit of wine, which not only enriches, but disposes all ordinary wines to grow fine.

If either by fraud or accident a larger portion of water is mixed with wine than is proper for its consistence, and no way necessary or essential, this superfluous water does not only deprave the taste, and spoil the excellence of the wine, but also renders it less durable; for humidity in general, and much more a superfluous aqueous humidity, is the primary and restless instrument of all the changes that are brought on by fermentation. It may doubtless therefore be useful, and sometimes absolutely necessary, to take away this superfluous water from the other part which strictly and properly constitutes the wine. This has been agreed upon all hands as a thing proper, but the manner of doing it has not been well agreed on: some have proposed the sucking it by means of heat and evaporation, others by percolation, and others by various other methods, all found unsuccessful when brought to the trial; but the way proposed by Dr Shaw from Stahl, is the most certain and commodious; this is done by a concentration of the wine, not by means of heat, but of cold.

If any kind of wine, but particularly such as has never been adulterated, be in a sufficient quantity, as that of a gallon or more, exposed to a sufficient degree of cold in frosty weather, or be put into any place where ice continues all the year, as in our ice-houses, and there suffered to freeze, the superfluous water that was originally contained in the wine will be frozen into ice, and will leave the proper and truly essential part of the wine unfrozen, unless the degree of cold should

Wine. should be very intense, or the wine but weak and poor. This is the principle on which Stahl founds his whole system of condensing wines by cold. When the froit is moderate, the experiment has no difficulty, because not above a third or a fourth part of the superfluous water will be froze in a whole night; but if the cold be very intense, the best way is, at the end of a few hours when a tolerable quantity of ice is formed, to pour out the remaining fluid liquor, and set it in another vessel to freeze again by itself. If the vessel, that thus by degrees receives the several parcels of the condensed wine, be suffered to stand in the cold freezing place where the operation is performed, the quantity lying thin in the pouring out, or otherwise, will be very apt to freeze anew; and if it be set in a warm place, some of this aqueous part thaws again, and so weakens the rest. The condensed wine therefore should be emptied in some place of a moderate degree as to cold or heat, where neither the ice may dissolve, nor the vinous substance mixed among it be congealed. But the best expedient of all is to perform the operation with a large quantity of wine, or that of several gallons, where the utmost exactness, or the danger of a trifling waste, need not be regarded.

By this method, when properly performed, there first freezes about one third part of the whole liquor; and this is properly the more purely aqueous part of it, inasmuch that when all the vinous fluid is poured off to be again exposed to a concentration, the ice remaining behind from this first freezing being set to thaw in a warm place, dissolves into a pure and tasteless water. The frozen part, or ice, consists only of the watery part of the wine, and may be thrown away, and the liquid part retains all the strength, and is to be preserved. This will never grow four, musty, or mouldy afterwards, and may at any time be reduced to wine of the common kind again, by adding to it as much water as will make it up to the quantity that it was before.

Wines in general may by this method be reduced to any degree of vinosity or perfection.

The benefit and advantage of this method of congelation, if reduced to practice in the large way in the wine countries, must be evident to every body. Concentrated wines in this manner might be sent into foreign countries instead of wine and water, which is what is usually now sent, the wines they export being loaded, and in danger of being spoiled by three or four times their own quantity of unnecessary, superfluous, and prejudicial water.

An easy method of recovering pricked wines may be learned from the following experiment: Take a bottle of red port that is pricked, add to it half an ounce of tartarized spirit of wine, shake the liquor well together, and set it by for a few days, and it will be found very remarkably altered for the better.

This experiment depends upon the useful doctrine of acids and alkalies. All perfect wines have naturally some acidity, and when this acidity prevails too much, the wine is said to be pricked, which is truly a state of the wine tending to vinegar: but the introduction of a fine alkaline salt, such as that of tartar, imbibed by spirit of wine, has a direct power of taking off the acidity, and the spirit of wine also contributes to this, as a great preservative in general of wines. If this ope-

ration be dexterously performed, pricked wines may be absolutely recovered by it, and remain saleable for some time; and the same method may be used to malt liquors just turned sour.

The age of wine is properly reckoned by leaves; thus they say wine of two, four, or six leaves, to signify wine of two, four, or six years old; taking each new leaf put forth by the vine since the wine was made for a year.

WINE is also a denomination applied in medicine and pharmacy to divers mixtures and compositions, wherein the juice of the grape is a principal ingredient. See the article VINUM.

With regard to the medical uses of wines, it is observed, that among the great variety of wines in common use among us, five are employed in the shops as menstrua for medicinal simples; that is, the *vinum album hispanicum*, or Mountain wine; the *vinum album gallicum*, or French white wine; the Canary wine, or sack, the Rhenish wine, and the red port. The effects of these liquors on the human body are, to cheer the spirits, warm the habit, promote perspiration, render the vessels full and turgid, raise the pulse, and quicken the circulation. The effects of the full bodied wines are much more durable than those of the thinner: all sweet wines, as Canary, abound with a glutinous, nutritious substance, whilst the others are not nutritive, or only accidentally so, by strengthening the organs employed in digestion. Sweet wines, in general, do not pass off freely by urine; and they heat the constitution more than an equal quantity of any other, though containing full as much spirit: red port, and most of the red wines, have an astringent quality, by which they strengthen the tone of the stomach, and thus prove serviceable for restraining immoderate secretions; those which are of an acid nature, as Rhenish, pass freely by the kidneys, and gently loosen the belly. It is supposed that these last exasperate and occasion gouty calculous disorders, and that new wines of every kind have this effect.

WINE Spirit, a term used by our distillers, and which may seem to mean the same thing with the phrase of spirit of wine: but they are taken in very different senses in the trade.

Spirit of Wine is the name given to the common malt spirit when reduced to an alcohol or totally inflammable state; but the phrase *wine-spirit* is used to express a very clean and fine spirit, of the ordinary proof strength, and made in England from wines of foreign growth.

The way of producing it is by simple distillation, and it is never rectified any higher than common bubble proof. The several wines of different natures yield very different proportions of spirit; but, in general, the strongest yield one fourth, the weakest in spirits one eighth, part of proof spirit; that is, they contain from a sixteenth to an eighth part of their quantity of pure alcohol.

Wines that are a little four serve not at all the worse for the purposes of the distiller; they rather give a greater vinosity to the produce. This vinosity is a thing of great use in the wine-spirit, whose principal use is to mix with another that is tartarized, or with a malt-spirit, rendered alkaline by the method of rectification. All the wine-spirits made in England,

even

even those from the French wines, appear very greatly different from the common French brandy; and this has given our distillers a notion that there is some secret art practised in France, for the giving the agreeable flavour to that spirit: but this is without foundation.

WING, that part of a bird, insect, &c. whereby it is enabled to fly. See BIRD and ORNITHOLOGY.

WINGS, in military affairs, are the two flanks or extremes of an army, ranged in form of a battle; being the right and left sides thereof.

WINTER, one of the four seasons or quarters of the year. See SEASON, &c.

Winter commences on the day when the sun's distance from the zenith of the place is greatest, and ends on the day when its distance is at a mean between the greatest and least.

Under the equator, the winter as well as other seasons return twice every year; but all other places have only one winter in the year; which in the northern hemisphere begins when the sun is in the tropic of Capricorn, and in the southern hemisphere when in the tropic of Cancer; so that all places in the same hemisphere have their winter at the same time.

WIRE, a piece of metal drawn through the hole of an iron into a thread of a fineness answerable to the hole it passed through.

Wires are frequently drawn so fine as to be wrought along with other threads of silk, wool, flax, &c.

The metals most commonly drawn into wire, are gold, silver, copper, and iron. Gold-wire is made of cylindrical ingots of silver, covered over with a skin of gold, and thus drawn successively through a vast number of holes, each smaller and smaller, till at last it is brought to a fineness exceeding that of a hair. That admirable ductility which makes one of the distinguishing characters of gold, is no where more conspicuous than in this gilt wire. A cylinder of 48 ounces of silver, covered with a coat of gold, only weighing one ounce, as Dr Halley informs us, is usually drawn into a wire, two yards of which weigh no more than one grain; whence 98 yards of the wire weigh no more than 49 grains, and one single grain of gold covers the 98 yards; so that the ten thousandth part of a grain is above one-eighth of an inch long.

WIRE of Lapland. The inhabitants of Lapland have a sort of shining slender substance in use among them on several occasions, which is much of the thickness and appearance of our silver-wire, and is therefore called, by those who do not examine its structure or substance, *Lapland wire*. It is made of the sinews of the rein-deer; which being carefully separated in the eating, are, by the women, after soaking in water and beating, spun into a sort of thread, of admirable fineness and strength, when wrought to the smallest filaments; but when larger, is very strong, and fit for the purposes of strength and force. Their wire, as it is called, is made of the finest of these threads, covered with tin. The women do this business; and the way, they take is to melt a piece of tin, and placing at the edge of it a horn, with a hole through it, they draw these sinewy threads, covered with the tin, through the hole, which prevents their coming out too thick covered. This drawing is performed with their teeth; and there is a small piece of bone placed at the top of the hole, where the wire is made flat; so that we al-

ways find it rounded on all sides but one, where it is flat.

This wire they use in embroidering their cloaths as we do gold and silver; they often sell it to strangers, under the notion of its having certain magical virtues.

WISDOM, usually denotes a higher and more refined notion of things immediately presented to the mind, as it were, by intuition, without the assistance of ratiocination.

Sometimes the word is more immediately used, in a moral sense, for what we call *prudence*, or *discretion*, which consists in the soundness of the judgment, and a conduct answerable thereto.

WIT is a quality of certain thoughts and expressions: the term is never applied to an action nor to a passion, and as little to an external object.

However difficult it may be, in every particular instance, to distinguish a witty thought or expression from one that is not so; yet in general it may be laid down, that the term *wit* is appropriated to such thoughts and expressions as are ludicrous, and also occasion some degree of surprise by their singularity. Wit also, in a figurative sense, expresses that talent which some men have of inventing ludicrous thoughts or expressions: we say commonly, a *witty man*, or a *man of wit*.

Wit, in its proper sense, as explained above, is distinguishable into two kinds; wit in the thought, and wit in the words or expression. Again, wit in the thought is of two kinds; ludicrous images, and ludicrous combinations of things that have little or no natural relation.

Ludicrous images that occasion surprise by their singularity, as having little or no foundation in nature, are fabricated by the imagination: and the imagination is well qualified for the office; being of all our faculties the most active, and the least under restraint. Take the following example.

Shylock. You knew (none so well, none so well as you) of my daughter's flight.

Salino. That's certain. I, for my part, knew the taylor that made the wings she flew withal.

Merchant of Venice, act 3. sc. 1.

The image here is undoubtedly witty. It is ludicrous: and it must occasion surprise; for having no natural foundation, it is altogether unexpected.

The other branch of wit in the thought, is that only which is taken notice of by Addison, following Locke, who defines it "to lie in the assemblage of ideas; and putting those together, with quickness and variety, wherein can be found any resemblance or congruity, thereby to make up pleasant pictures and agreeable visions in the fancy." It may be defined more curiously, and perhaps more accurately, a junction of things by distant and fanciful relations, which surprise because they are unexpected." The following is a proper example:

We grant although he had much wit,
H' was very shy of using it,
As being loth to wear it out;
And therefore bore it not about,
Unless on holidays, or so,
As men their best apparel do.

Hudibras, canto 1.

Wit is of all the most elegant recreation: the image enters the mind with gaiety, and gives a sudden flash which is extremely pleasant. Wit thereby gently ele-

valates

Wisdom,
Wit.

Wit. vates without flaining, raises mirth without dissolute-
ness, and relaxes while it entertains.

Wit, in the expression, commonly called a *play of words*, being a bastard sort of wit, is reserved for the last place. We proceed to examples of wit in the thought; and first of ludicrous images.

Falstaff, speaking of his taking Sir John Coleville of the Dale:

Here he is, and here I yield him; and I beseech your grace, let it be book'd with the rest of this day's deeds; or, by the Lord, I will have it in a particular ballad else, with mine own picture on the top of it, Coleville kissing my foot: to the which course if I be enforced, if you do not all shew like gilt twopences to me; and I, in the clear sky of fame, o'ershine you as much as the full moon doth the cinders of the element, which shew like pins' heads to her: believe not the word of the noble. Therefore let me have right, and let desert mount.

Second Part, Henry IV. act 4. sc. 6.

I knew, when seven justices could not take up a quarrel, but when the parties were met themselves, one of them thought but of an *if*; as, if you had said so, then I said so; and they hook hands, and fwoe brothers. Your *if* is the only peace-maker; much virtue is in *if*. *Shakespeare.*

For there is not through all nature another so callous and insensible a member as the world's posteriors, whether you apply to it the toe or the birch.

Preface to a Tale of a Tub.

The other branch of wit in the thought, viz. ludicrous combinations and oppositions, may be traced through various ramifications. And, first, fanciful causes assigned that have no natural relation to the effects produced.

Lancaster. Fare you well, Falstaff; I, in my condition, shall better speak of you than you deserve. *[Exit.]*

Falstaff. I would you had but the wit; 'twere better than your dukedom. Good faith, this same young sober-blooded boy doth not love me; nor a man cannot make him laugh: but that's no marvel, he drinks no wine. There's never any of these demure boys come to any proof; for thin drink doth so overcool their blood, and making many fish-meals, that they fall into a kind of male green-sickness; and then, when they marry, they get wenches. They are generally fools and cowards; which some of us should be too, but for inflammation. A good therris-sack hath a twofold operation in it: it ascends me into the brain; dries me there all the foolish, dull, and crudy vapours which environ it; make it apprehensive, quick, forgetive, full of nimble, fiery, and delectable shapes; which delivered o'er to the voice, the tongue, which is the birth, becomes excellent wit. The second property of your excellent therris is, the warming of the blood; which before cold and settled, left the liver white and pale; which is the badge of pusillanimity and cowardice; but the therris warms it, and makes it course from the inwards to the parts extreme; it illuminateth the face, which, as a beacon, gives warning to all the rest of this little kingdom, man, to arm; and then the vital commoners and inland petty spirits muster me all to their captain, the heart; who, great and

puffed up with his retinue, doth any deed of courage: and thus valour comes of therris. So that skill in the weapon is nothing without sack, for that sets it a-work; and learning a mere hoard of gold kept by a devil, till sack commences it, and sets it in act and use. Hereof comes it that Prince Harry is valiant; for the cold blood he did naturally inherit of his father, he hath, like lean, sterile, and bare land, manured, husbanded, and till'd with excellent endeavour of drinking good and good store of fertile therris, that he is become very hot and valiant. If I had a thousand sons, the first human principle I would teach them, should be to forswear thin potations, and to add themselves to sack.

Second Part of Henry IV. act 4. sc. 7.

The trenchant blade, toledo trusty,
For want of fighting was grown rusty,
And ate into itself, for lack
Of some body to hew and hack.
The peaceful scabbard where it dwelt
The rancor of its edge had felt:
For of the lower end two handful
It had devoured, 'twas so manifold;
And so much scorn'd to lurk in case,
As if it durst not shew its face.

Hudibras, canto 1.

To account for effects by such fantastical causes, being highly ludicrous, is quite improper in any serious composition. Therefore the following passage from Cowley, in his poem on the death of Sir Henry Wootton, is in a bad taste.

He did the utmost bounds of knowledge find,
He found them not so large as was his mind.
But, like the brave Pellean youth, did moan,
Because that art had no more worlds than one.
And when he saw that he through all had pass'd,
He dy'd, lest he should idle grow at last.

Fanciful reasoning:

Falstaff. Imbowell'd!—if thou imbowel me to-day, I'll give you leave to powder me, and eat me to-morrow! S'blood, 'twas time to counterfeit, or that hot termagant Scot had paid me scot and lot too. Counterfeit? I lie, I am no counterfeit: to die is to be a counterfeit; for he is but the counterfeit of a man, who hath not the life of a man; but to counterfeit dying, when a man thereby liveth, is to be no counterfeit, but the true and perfect image of life indeed.

First Part Henry IV. act 1. sc. 10.

Clown. And the more pity that great folk should have countenance in this world to drown or hang themselves, more than their even Christians.

Hamlet, act 5. sc. 2.

Pedro. Will you have me, Lady?

Beatrice. No, my Lord, unless I might have another for working days. Your Grace is too costly to wear every day.

Much ado about Nothing, act 2. sc. 5.

Jessica. I shall be saved by my husband; he hath made me a Christian.

Launcelot. Truly the more to blame he; we were Christians enough before, e'en as many as could well live by one another: this making of Christians will raise the price of hogs; if we grow all

Montgolfier's B.

all to be pork-eaters, we shall not have a rather on the coals for money.

Merchant of Venice, act 3. sc. 6.

But Hudibras gave him a twitch,
As quick as lightning, in the breech,
Just in the place where honour's lodg'd,
As wise philosophers have judg'd;
Because a kick in that part, more
Hurts honour, than deep wounds before.

Hudibras, canto 3.

Indicrous junction of small things with great, as of equal importance :

This day black omens threat the brightest fair
That e'er deserv'd a watchful spirit's care :
Some dire disaster, or by force or flight :
But what, or where, the fates have wrapt in night :
Whether the nymph shall break Diana's law ;
Or some frail china jar receive a flaw :
Or stain her honour, or her new brocade ;
Forget her pray'rs, or miss a masquerade ;
Or lose her heart, or necklace, at a ball ;
Or whether Heaven has doom'd that Shock must fall.

Rape of the Lock, canto ii. 101.

One speaks the glory of the British Queen,
And one describes a charming Indian screen.

Ibid. canto iii. 13.

Then flash'd the living lightning from her eyes,
And screams of horror rend th' affrighted skies.
Not louder shrieks to pitying heav'n are cast,
When husbands, or when lap-dogs, breathe their last ;
Or when rich china vessels, fall'n from high,
In glittering dust and painted fragments lie !

Ibid. canto iii. 155.

Not youthful kings in battle seiz'd alive,
Not scornful virgins who their charms survive,
Not ardent lovers robb'd of all their bliss,
Not ancient ladies when refus'd a kiss,
Nor tyrants fierce that unrepenting die,
Nor Cynthia when her manteau's pinn'd awry,
E'er felt such rage, resentment, and despair,
As thou, sad virgin ! for thy ravish'd hair.

Ibid. canto iv. 3.

Joining things that in appearance are opposite. As for example, where Sir Roger de Coverley, in the Spectator, speaking of his widow,

That he would have given her a coal-pit to have kept her in clean linen ; and that her finger should have sparkled with one hundred of his richest acres.

Premises that promise much and perform nothing. Cicero upon this article says,

Sed scitis esse notissimum ridiculi genus, cum aliud expectamus, aliud dicitur : hic nobismetipsi nostre erroris sumus movet.

De oratore, l. 2. c. 63.

Beatrice.—With a good leg and a good foot, uncle, and money enough in his purse, such a man would win any woman in the world, if he could get her good will.

Much ado about Nothing, act. 2. sc. 1.

Beatrice. I have a good eye, uncle, I can see a church by day-light.

Having discuss'd wit in the thought, we proceed to what is verbal only, commonly call'd a *play of words*. This sort of wit depends, for the most part, upon choosing a word that hath different significations : by

this artifice, hocus-pocus tricks are played in language ; and thoughts plain and simple take on a very different appearance. Play is necessary for man, in order to refresh him after labour ; and accordingly man loves play : he even relishes a play of words : and it is happy for us, that words can be employed, not only for useful purposes, but also for our amusement. This amusement accordingly, though humble and low, is relished by some at all times, and by all at some times, in order to unbend the mind.

It is remarkable, that this low species of wit has, at one time or other, made a figure in most civilized nations, and has gradually gone into disrepute. So soon as a language is formed into a system, and the meaning of words is ascertained with tolerable accuracy, opportunity is afforded for expressions, which, by the double meaning of some words, give a familiar thought the appearance of being new ; and the penetration of the reader or hearer is gratified, in detecting the true sense disguised under the double meaning.—That this sort of wit was in England deemed a reputable amusement, during the reigns of Elizabeth and James I. is vouched by the works of Shakespear, and even by the writings of grave divines. But it cannot have any long endurance : for as language ripens, and the meaning of words is more and more ascertained, words held to be synonymous diminish daily ; and when those that remain have been more than once employed, the pleasure banisheth with the novelty.

We proceed to examples, which, as in the former case, shall be distributed into different classes.

A seeming resemblance from the double meaning of a word :

Beneath this stone my wife doth lie ;
She's now at rest, and so am I.

A seeming contrast from the same cause, termed a *verbal antithesis*, which hath no depicable effect in ludicrous subjects :

Whilst Iris his cosmetic wash would try
To make her bloom revive, and lovers die.
Some ask for charms, and others philters chuse,
To gain Corinna, and their quartans lose.

Dispensary, canto 2.

And how frail nymphs, oft, by abortion, aim
To lose a substance, to preserve a name.

Ibid. canto 3.

While nymphs take treats, or assignations give.

Rape of the Lock.

Other seeming connections from the same cause :

Will you employ your conqu'ring sword,
To break a fiddle and your word ?

Hudibras, canto 2.

To whom the knight with comely grace
Put off his hat to put his case.

Hudibras, part 3. canto 3.

Here Britain's statesman oft the fall foredoom
Of foreign tyrants, and of nymphs at home ;
Here thou, great Anna ! whom three realms obey,
Dost sometimes counsel take—and sometimes tea.

Rape of the Lock, canto 3. l. 5.

O'er their quietus where fat judges dose,
And lull their cough and conscience to repose.

Dispensary, canto 1.

Wit. Speaking of Prince Eugene :

This general is a close taker of snuff as well as of towns. *Pope, Key to the Lock.*

Exul mentisque domusque.

Metamorphoses, lib. ix. 439.

A seeming opposition from the same cause :

Hic quiescit qui nunquam quievit.

Again,

So like the chances are of love and war,

That they alone in this distinguish'd are ;

In love the victors from the vanquish'd fly,

They fly that wound, and they pursue that die.

Waller.

What new-found witchcraft was in thee,

With thine own cold to kindle me ?

Strange art ; like him that should devise

To make a burning-glass of ice. *Cowley.*

Wit of this kind is unsuitable in a serious poem ; witness the following line in Pope's *Elegy* to the memory of an unfortunate lady :

Cold is that breath which warm'd the world before.

This sort of writing is finely burlesqued by Swift :

Her hands, the softest ever felt,

Though cold would burn, though dry would melt.

Strepson and Chloe.

Taking a word in a different sense from what it meant, comes under wit, because it occasions some slight degree of surprise :

Beatrice. I may sit in a corner, and cry *Heigh ho !* for a husband.

Pedro. Lady Beatrice, I will get you one.

Beatrice. I would rather have one of your father's getting. Hath your Grace ne'er a brother like you ? Your father got excellent husbands, if a maid could come by them.

Much ado about Nothing, act 1. sc. 5.

Falstaff. My honest lads, I will tell you what I am about.

Pistol. Two yards and more.

Falstaff. No quips now, Pistol : indeed I am in the waist two yards about : but I am now about no waste ; I am about thrift.

Merry Wives of Windsor, act 1. sc. 7.

Lo. Sands.—By your leave, sweet ladies, If I chance to talk a little wild, forgive me : I had it from my father.

Anne Bullen. Was he mad, Sir ?

Sands. O, very mad, exceeding mad, in love too ? But he would bite none— *K. Henry VIII.*

An assertion that bears a double meaning, one right, one wrong, but so connected with other matters as to direct us to the wrong meaning, is a species of *ballard wit* which is distinguished from all others, by the name *pun*. For example,

Paris.—Sweet Helen, I must woo you

To help unarm our Hector : his stubborn buckles,

With these your white enchanting fingers touch'd,

Shall more obey, than to the edge of steel,

Or force of Greekish sinews ; you shall do more

Than all the island kings, disarm great Hector.

Trailus and Cressida, act 3. sc. 2.

The pun is in the close. The word *disarm* has a double meaning : it signifies to take off a man's armour, and also to subdue him in fight. We are directed to the latter sense by the context ; but with regard to Helen, the word holds only true in the former sense. We go on with other examples :

Esse nihil dicis quicquid petis, improbe Cinna :

Si nil, Cinna, petis, nil tibi, Cinna, nego.

Martial, l. 3. epigr. 61.

Chief Justice. Well ! the truth is, Sir John, you live in great infamy.

Falstaff. He that buckles him in my belt cannot live in less.

Chief Justice. Your means are very slender, and your waist is great.

Falstaff. I would it were otherwise : I would my means were greater, and my waist slenderer.

Second Part Henry IV. act 1. sc. 5.

Celia. I pray you bear with me, I can go no further.

Clown. For my part, I had rather bear with you than bear you : yet I should bear no cross if I did bear you ; for I think you have no money in your purse.

As you like it, act 2. sc. 4.

He that imposes an oath makes it,

Not he that for convenience takes it.

Then how can any man be said :

To break an oath he never made ?

Hudibras, part 2. canto 2.

The seventh satire of the first book of Horace is purposely contrived to introduce at the close a most execrable pun. Talking of some infamous wretch whose name was *Rex Rupilius*,

Perseus exclamat, Per magnos, Brute, deos te

Oro, qui reges confusis tollere, cur non

Hunc regem jugulas ? Operum hoc, mihi crede, tuorum est.

Though playing with words is a mark of a mind at ease, and disposed to any sort of amusement, we must not thence conclude that playing with words is always ludicrous. Words are so intimately connected with thought, that if the subject be really grave, it will not appear ludicrous even in this fantastic dress. We are, however, far from recommending it in any serious performance : on the contrary, the discordance between the thought and expression must be disagreeable : witness the following specimen :

He hath abandoned his physicians, Madam, under whose practices he hath persecuted time with hope ; and finds no other advantage in the process, but only the losing of hope by time.

All's well that ends well, act 1. sc. 1.

K. Henry. O my poor kingdom, sick with civil broils !

When that my care could not withhold thy riots, What wilt thou do when riot is thy care ?

Second part Henry IV.

If any one shall observe, that there is a third species of wit, different from those mentioned, consisting in sounds merely, we are willing to give it place. And indeed it must be admitted, that many of *Hudibras's* double rhymes come under the definition of wit given in the beginning of this article : they are ludicrous, and

and their singularity occasions some degree of surprise. Swift is not less successful than Butler in this sort of wit; witness the following instances: *Goddesse—Bodice. Pliny—Nicolini. Ifcaristi—Chariots. Mitre—Nitre. Dragon—Suffragan.*

A repartee may happen to be witty: but it cannot be considered as a species of wit; because there are many repartees extremely smart, and withal extremely serious. We give the following example: A certain petulant Greek, objecting to Anacharsis that he was a Scythian: "True (says Anacharsis) my country disgraces me, but you disgrace your country." This fine turn gives surprise; but it is far from being ludicrous.

WIT (John de), a celebrated pensioner of Holland, and one of the greatest politicians of his time, was the son of Jacob de Wit, burgomaster of Dort, and was born in 1625. He became well skilled in civil law, politics, mathematics, and other sciences; and wrote a treatise on the Elements of Curved Lines, published by Francis Schooten. Having taken his degree of doctor of law, he travelled into foreign courts, where he became esteemed for his genius and prudence. At his return to his native country in 1650, he became pensionary of Dort, then counsellor-pensionary of Holland and West-Friesland, intendant and register of the siefs, and keeper of the great seal. He was thus at the head of affairs in Holland; but his opposition to the re-establishment of the office of stadtholder, which he thought a violation of the freedom and independence of the republic, cost him his life, when the prince of Orange's party prevailed. He and his brother Cornelius were assassinated by the populace at the Hague in 1674, aged 47.

WITCHCRAFT, a kind of sorcery, especially in women. See SORCERY.

WITENA MOT, or WITENA *Gemot*, among the Anglo Saxons, was a term which literally signified the assembly of the wise men; and was applied to the great council of the nation, of latter days called the *parliament*.

WITHERS of a HORSE, the juncture of the shoulder-bones at the bottom of the neck and mane, towards the upper part of the shoulder.

WITNESS, in law, a person who gives evidence in any cause, and is sworn to speak the truth, the whole truth, and nothing but the truth.

Trial by WITNESSES, a species of trial without the intervention of a jury. This is the only method of trial known to the civil law, in which the judge is left to form in his own breast his sentence upon the credit of the witnesses examined: but it is very rarely used in our law, which prefers the trial by jury before it in almost every instance. Save only that when a widow brings a writ of dower, and the tenant pleads that the husband is not dead; this being looked upon as a dilatory plea, is in favour of the widow, and for greater expedition allowed to be tried by witnesses examined before the judges: and so, faith Finch, shall no other case in our law. But Sir Edward Coke mentions some others: as to try whether the tenant in a real action was duly summoned, or the validity of a challenge to a juror: so that Finch's observation must be confined to the trial of direct and not collateral issues. And in every case Sir Edward Coke lays it down, that the affirmative must be proved by two witnesses at the least.

WITSIUS (Herman), a learned and eminent divine of North Holland, born at Enckhuisen in 1626. He was professor of divinity successively at Franeker, Utrecht, and Leyden; and applied himself successfully to oriental learning, of which his capital work *Ægyptiaca* affords sufficient proof. His Oeconomy of the Covenants between God and Man, is warmly recommended by Mr Hervey in his *Theron* and *Alpafio*. He died in 1708.

WITTENBERG, a city of Germany, capital of the circle of Upper Saxony, 50 miles north of Dresden. It is under immediate vassalage, and the seat of an aulic judicatory, a general superintendency, an inspection and consistory. The town is not large; but is well fortified, and contains a famous university, in which Melancthon was a professor. In this place Martin Luther first began to preach against the pope's indulgences; and in the cathedral of All Saints he is said to have been buried. In the old citadel of this town the ancient Saxon electors used to reside. Besides the university, there is a Latin school in the town, with six masters. The library belonging to the university is said to be very valuable. In 1756 the Prussians being masters of the town, destroyed a part of its fortifications.

WOAD, in botany. See ISATIS.

Woad not only affords a lasting and substantial blue, which, according to the scale of the dyers, may be reduced into many different shades, but is also of great use in dyeing and fixing many other colours. But notwithstanding this, and its being a commodity of our own, the use of it is very much declined since the introduction of indigo; for the purchase of which large sums go annually out of the nation. The reason of this is, that indigo affords a more lively and pleasing colour, is managed with more ease by the dyers, and does their business more expeditiously. Yet with all these advantages, it is universally acknowledged, that the colour which indigo affords is inferior to that of woad in many respects, and particularly in permanency: for which reason, they are frequently used in conjunction; woad to give solidity and substance, and indigo to give brightness and colour. But the worst consequence that has attended the use of indigo, is not barely lessening the consumption, but abating the price and depreciating the intrinsic value of woad; so that less care is taken in the management of it; to which in a great measure the inferiority of its colour, at least in some places, is at present owing. The declension in its consumption is not the case here only, but also in other countries; for it was once the great staple of Languedoc, and was cultivated also in Normandy, and in other provinces of France; as it also is in Spain, Portugal, the Azores, and Canary islands, Switzerland, in the neighbourhood of Geneva, in different parts of Germany, and in Sweden.

Our own woad was allowed to be superior to any that we imported; and yet before indigo had so great an ascendancy, it was thought necessary to lay high duties upon foreign woad, for the encouragement of the growing and manufacturing it here; which duties still subsist. If we consider, that this is a commodity in which agriculture is as much interested as our manufacturers, one cannot well doubt that the preserving and restoring it deserves great attention here, as well

attacked by the university, in defence of Edward earl of Clarendon, lord high-chancellor of England, and chancellor of the university, and was likewise animadverted upon by bishop Burnet; upon which he published a Vindication of the Historiographer of the University of Oxford. He died at Oxford of a retention of urine in 1695.

WOOD, a solid substance, whereof the trunks and branches of trees consist. The wood is all that part of a tree included between the bark and the pith. For the structure of the pith, bark, and wood of plants, see the article PLANT.

Composition for preserving Wood. See CHEMISTRY, n° 112, 149.

Staining or Dyeing of Wood for inlaying, &c. Red, is done by boiling the wood in water and alum; then taking it out, adding brazil to the liquor, and giving the wood another boil in it. Black, by brushing it over with logwood boiled in vinegar, hot; then washing it over with a decoction of galls and coppers till it be of the hue required. Any other colour may be given by squeezing out the moisture of horse-dung through a sieve, mixing it with dissolved rock-alum and gum arabic; and to the whole adding green, blue, or any other colour designed. After standing two or three days, pear-tree or other wood, cut to the thickness of half a crown, is put into the liquor boiling hot, and suffered to remain till it be sufficiently coloured.

WOOD, (*Silva*), in geography, a multitude of trees extended over a large continued track of land, and propagated without culture. The generality of woods only consist of trees of one kind.

The ancient Saxons had such a veneration for woods, that they made them sanctuaries.

It is ordained, that none shall destroy any wood, by turning it into tillage or pasture, &c. where there are two acres or more in quantity, on pain of forfeiting 40s. an acre, by 35 Henry VIII. c. 17. All woods that are felled at 14 years growth, are to be preserved from destruction for eight years; and no cattle put into the ground till five years after the felling thereof, &c. 13 Eliz. c. 25. The burning of woods, or underwood, is declared to be felony; also those persons that maliciously cut or spoil timber-trees, or any fruit-trees, &c. shall be sent to the house of correction, there to be kept three months, and whipt once a month.

Wood-Cock, in ornithology. See SCOLOPAX.

Wood-Louse. See ONISCUS.

Wood-Pecker. See PICUS.

WOODSTOCK, a town of Oxfordshire, in England, pleasantly seated on a rising ground, and on a rivulet; a well compacted borough-town, and sends two members to parliament; but is chiefly noted for Blenheim-house, a fine palace, built in memory of the victory obtained by the duke of Marlborough over the French and Bavarians in August 1704. It was erected at the public expence, and is one of the noblest seats in Europe. One of the passages to it is over a bridge with one arch, 190 feet in diameter, resembling the Rialto at Venice. The gardens take up 100 acres of ground; and the offices, which are very grand, have room enough to accommodate 300 people. The apartments of the palace are magnificently furnished; and the staircases, statues, paintings, and tapestry, surpris-

singly fine. The town is about half a mile from the palace, having several good inns; and a manufacture of steel chains for watches, and excellent gloves. It is 8 miles north of Oxford, and 60 west-north-west of London. W. Long. 1. 17. N. Lat. 51. 50.

WOODWARD (Dr John), was born in 1665, and educated at a country school, where he learned the Latin and Greek languages, and was afterwards sent to London, where he is said to have been put apprentice to a linen-draper. He was not long in that station, till he became acquainted with Dr Peter Barwick, an eminent physician, who took him under his tuition and into his family. Here he prosecuted with great vigour and success the study of philosophy, anatomy, and physic. In 1692, Dr Stillingfleet quitting the place of professor of physic in Gresham college, our author was chosen to succeed him, and the year following was elected F. R. S. In 1695 he obtained the degree of M. D. by patent from archbishop Tennison; and the same year he published his Essay toward a natural History of the Earth. He afterward wrote many other pieces, which have been well received by the learned world. He founded a lecture in the university of Cambridge, to be read there upon his Essay, &c. and handsomely endowed it. He died in 1728.

WOOF, among manufacturers, the threads which the weavers shoot across with an instrument called the *shuttle*. See CLOTH.

WOOL, the covering of sheep. See OVIS.

While the wool remains in the state it was first shorn off the sheep's back, and not sorted into its different kinds, it is called *fleece*.

Each fleece consists of wool of divers qualities and degrees of fineness, which the dealers therein take care to separate.

The French and English usually separate each fleece into three sorts, viz. 1. Mother-wool, which is that of the back and neck. 2. The wool of the tails and legs. 3. That of the breast and under the belly.

The Spaniards make the like division into three sorts, which they call *prime*, *second*, and *third*; and for the greater ease, denote each bale or pack with a capital letter, denoting the sort. If the triage or separation be well made, in 15 bales there will be 12 marked R, that is, refine, or prime; two marked F, for fine, or second; and one S, for thirds.

The wools most esteemed are the English, chiefly those about Leominster, Cotswold, and the Isle of White; the Spanish, principally those about Segovia; and the French, about Berry: which last are said to have this peculiar property, that they will knot or bind with any other sort; whereas the rest will only knot with their own kind.

Among the ancients, the wools of Attica, Megara, Laodicea, Apulia, and especially those of Tarentum, Parma, and Altino, were the most valued. Varro assures us, the people there used to clothe their sheep with skins, to secure the wool from being damaged.

WOOLSTON (Thomas), an English divine, was born at Northampton in 1669, and educated at Cambridge. His first appearance in the learned world was in 1705, in a work intitled, The old Apology for the Truth of the Christian Religion against the Jews and Gentiles

Gentiles revived. He afterward wrote many pieces: but what made the most noise, are his Six Discourses on the Miracles of Christ; which occasioned a great number of books and pamphlets upon the subject, and raised a prosecution against him. At his trial in Guildhall, before the lord chief-justice Raymond, he spoke several times himself; and urged, that "he thought it very hard that he should be tried by a set of men, who, though otherwise very learned and worthy persons, were no more judges of the subjects on which he wrote, than himself was a judge of the most crabbed points of the law." He was sentenced to a year's imprisonment, and to pay a fine of 100*l.* He purchased the liberty of the rules of the King's-bench, where he continued after the expiration of the year, being unable to pay the fine. The greatest obstruction to his deliverance from confinement was, the obligation of giving security not to offend by any future writings, he being resolved to write again as freely as before. He died in 1733.

WOOLWICH, a town in Kent, with a market on Fridays, but no fair. It is seated on the river Thames, and of great note for its fine docks and yards, where men of war are built; as also for its vast magazines of great guns, mortars, bombs, cannon-balls, powder, and other warlike stores. It has likewise an academy, where the mathematics are taught, and young officers instructed in the military art. It is nine miles east of London. E. Long. *o.* 10. N. Lat. 51. 30.

WORCESTER, in Latin *Wigornia*, the capital of a county of England of the same name, stands on the river Severn, but so low that it can hardly be seen till one is close upon it. It is supposed to be the *Brannonium* of Antoninus, the *Branogenium* of Ptolemy, and to have been built by the Romans to awe the Britons on the other side of the Severn. It was made an episcopal see about the year 680 by Sexulphus bishop of the Mercians; but the present cathedral was begun by Wulstun in the year 1084. The town hath been several times burnt down: first, in 1041, by Hardicanute, who also massacred the citizens; secondly, not long after William Rufus's time; and a third time, when king Stephen besieged and took it. Here, in latter times, was fought that battle, in which Charles II. with his Scots army, was defeated by Cromwell. In a garden, near the south gate of the city, where the action was hottest, the bones of the slain are often dug up. It had formerly strong walls and a castle; but these have been demolished long ago. It is now a large city, the streets broad and well paved, and some of them very regular and well built, particularly Foregate-street; so that in general it is a very agreeable place. The cathedral is a stately edifice, and among other monuments in it are those of king John, of Arthur, elder brother to Henry VIII. and of the countess of Salisbury, who gave occasion to the institution of the order of the Garter. There are seven or eight hospitals in and about the city; of which that built and endowed by Robert Berkeley of Spetchley, esq; is a very noble one. There is a school founded by Henry VIII. three other schools, and six charity schools. The Guildhall, and the workhouse, are stately structures. The churches, St Nicholas and All-Saints, have been lately rebuilt, and are very hand-

some edifices. The city carries on a great trade; for which it is chiefly indebted to its situation upon the Severn. A prodigious number of people are employed in and about it in the manufacture of broad-cloth and gloves. The Welch inhabit a part of it, and speak their own language. Its market is well supplied with provisions, corn, and cattle, and its quay is much frequented by ships. By a charter from James I. it is governed by a mayor, six aldermen, who are justices of the peace, and chosen out of 24 capital citizens, a sheriff, the city being a county of itself, a common council, consisting of 48 other citizens, out of which two chamberlains are yearly chosen, a recorder, town-clerk, two coroners, a sword bearer, 13 constables, and four serjeants at mace. Of the bishops of this see, there have been, it is said, one pope, four saints, seven lord high-chancellors, 11 archbishops, two lord treasurers, one chancellor to the queen, one lord president of Wales, and one vice-president. The city at present gives title of earl and marquis to the duke of Beaufort.

WORCESTERSHIRE, a county of England, bounded by Warwickshire on the east, by Gloucestershire on the south, by the counties of Hereford and Salop on the west, and on the north by Staffordshire. According to Templeman, it is 36 miles in length, 28 in breadth, and about 130 in circumference, within which it contains 700, and a part of two others, 11 market towns, of which three are boroughs, one city, namely *Worcester*, 152 parishes, about 540,000 acres, and 103,000 inhabitants.

This being an inland county, well cultivated, and free from lakes, marshes, or stagnant waters, the air is very sweet and wholesome all over it. The soil in general is very rich, producing corn, fruit, especially pears, of which they make a great deal of perry, hops, and pasture. The hills are covered with sheep, and the meadows with cattle. Hence they have wool, cloth, fluffs, butter, and cheese in abundance. They are also well supplied with fuel, either wood or coal, and salt from their brine pits and salt springs. Of the last they have not only enough for themselves, but export large quantities by the Severn; which noble river, to the great convenience and emolument of the inhabitants, runs from north to south through the very middle of the county, enriching the soil, and yielding it plenty of fish, and an easy expeditious conveyance of goods to and from it. The other rivers by which it is watered are the Stour, Avon, Teme, &c. It sends nine members to parliament, viz. two for the county, two for the city of Worcester, two for Droitwich, two for Evesham, and one for Bewdley; and lies in the diocese of Worcester, and Oxford circuit.

WORD, in language, an articulate sound designed to represent some idea. See *GRAMMAR* and *LANGUAGE*. See also *LOGIC*, Part I. chap. 1.

WORD, or *Watch-Word*, in military affairs, is some peculiar word or sentence, by which the soldiers know and distinguish one another in the night, &c. and by which spies and designing persons are discovered. It is used also to prevent surprises. The word is given out in an army every night to the lieutenant, or major-general of the day, who gives it to the majors of the brigades, and they to the adjutants; who give it first to the field-officers, and afterwards to a serjeant of each

Worcester-
shire,
Word.

Word
Worm.

each company, who carry it to the subalterns. In garrisons it is given after the gate is shut to the town-major, who gives it to the adjutants, and they to the serjeants.

Words of Command. See EXERCISE and MANUAL.

Signals by the Drum, made use of in exercising of the Army, instead of the Word of Command, viz.

Signals by the drum.

Operations.

A short roll,

To caution.

A flam,

To perform any distinct thing.

To arms,

To form the line or battalion.

The march,

To advance, except when intended for a salute.

The quick march,

To advance quick.

The point of war,

To march and charge.

The retreat,

To retreat.

Drum ceasing,

To halt.

Two short rolls,

To perform the flank firing.

The dragon march,

To open the battalion.

The grenadier march,

To form the column.

The troop,

To double divisions.

The long roll,

To form the square.

The grenadier march,

To reduce the square to the column.

The preparative,

To make ready and fire.

The general,

To cease firing.

Two long rolls,

To bring or lodge the colours.

WORLD, the assemblage of parts which compose the globe of the earth. See GEOGRAPHY and ASTRONOMY.

WORM, in gunnery, a screw of iron, to be fixed on the end of a rammer, to pull out the wad of a firelock, carabine, or pistol, being the same with the wad-hook, only the one is more proper for small arms, and the other for cannon.

WORM, in chemistry, is a long, winding pewter pipe, placed in a tub of water, to cool and condense the vapours in the distillation of spirits.

Blind-Worm, or Slow-Worm. See ANGUIS, n° 2.

Earth-Worm. See LUMBRICUS.

Glow-Worm. See GLOW-Worm.

Silk-Worm. See SILK-Worm.

WORMS, VERMES, in natural history. See ZOOLOGY.

WORMS in the human body. See MEDICINE, n° 493, and p. 4868.

WORMS in horses. See FARRIERY, § xv. and the article BLATTA.

WORMS, in dogs. See DOG, art. 4.

WORMS for bait. See FISHING.

WORMS, an ancient, large, and famous city of Germany, in the palatinate of the Rhine, with a bishop's see, whose bishop is a sovereign and prince of the empire. It is a free and imperial city, and the inhabitants are protefants. In the war of 1689, it was taken by the French, who almost reduced it to ashes.—The bishop lately built a new palace in it; and it is famous for a diet held here in 1521, at which Luther assisted in person. The Protefants have lately built a handsome church, where Luther is represented as appearing at the diet. It is noted for the excellent wine that grows in the neighbourhood, which they call *our Lady's milk*. In the campaign of 1743, king Geo. II. took up his quarters in this city, and lodged at the bishop's palace after the battle of Dettingen. It is

seated on the western bank of the Rhine, 14 miles N. W. of Heidelberg, 20 S. E. of Mentz, and 32 S. W. of Frankfurt. E. Long. 8. 27. N. Lat. 40. 34.

WORMING of dogs. All spaniels have certain strings under their tongues, by most called a *worm*; this must be taken out when they are about two months old, with the help of a sharp knife to slit it, and a shoemaker's awl to raise it up; you must be careful to take all out, or else your pains is to little purpose; for till then he will be hardly ever fat and right, in regard the worm or string will grow foul and troublesome, and hinder his rest and eating. This operation is generally recommended as a preventative of madness in dogs, or at least as disabling them, if mad, from biting in that condition.

WORMIUS (Olaus), a learned Danish physician, born in 1588 at Arhusen in Jutland. After beginning his studies at home, he studied at several foreign universities, and travelled to various parts of Europe for improvement. He returned to his native country in 1613, and was made professor of the belles lettres in the university of Copenhagen. In 1615, he was translated to the chair of the Greek professor; and in 1624 to the professorship of physic, which he held to his death. These occupations did not hinder him from practising in his profession, and from being the fashionable physician: the king and court of Denmark always employed him; and Christian IV. as a recompense for his services, conferred on him a canonry of Lunden. He published some pieces on subjects relating to his profession, several works in defence of Aristotle's philosophy, and several concerning the antiquities of Denmark and Norway; for which latter he is principally regarded, as they are very learned, and contain many curious particulars. He died in 1654.

WORMWOOD, in botany. See ARTEMISIA.

WORSHIP, the offering up of adoration, prayer, praise, thanksgiving, and confession to God, as our Creator, Benefactor, Lawgiver, and Judge. See MORALS, n° 174—176.

WORT, the infusion of malt, of which beer is made.—The uses of this infusion in common affairs is well known. By Dr M'Bride it has lately been found to have a strong antiseptic virtue, and to be useful in preventing the scurvy and other diseases to which sailors are liable; which was confirmed by capt. Cook in his late voyages. See *Means of preserving the health of SEAMEN*.

WOTTON (Sir Henry), an eminent writer, was the son of Thomas Wotton, esq; and was born in 1568. He studied for some time at New-college, Oxford, whence he removed to Queen's-college, where he made a great progress in logic and philosophy; wrote a tragedy for the use of that college, called *Tancred*; and afterwards received the degree of master of arts. After this, leaving the university, he travelled into France, Germany, and Italy; and having spent about nine years abroad, he returned to England, and became secretary to Robert earl of Essex, with whom he continued till that earl was apprehended for high-treason. He then retired to Florence, where he became known to the grand duke of Tuscany, who sent him privately with letters to James VI. king of Scotland, under the name of *Octavio Baldi*, to inform that king of a design against his life. Some months

Worm
Wotte

otton. months after, he went back to Florence; but king James coming to the possession of the crown of England, Mr Wotton returned home, was knighted by his majesty, and sent ambassador to the republic of Venice; and afterwards was employed in many other embassies to that and other courts; but the only reward he obtained for these services was his having the provostship of Eton conferred upon him about the year 1623, which he kept till his death, which happened in 1639. After his decease some of his manuscripts and printed tracts were published together in a volume, intitled, *Reliquiæ Wottonianæ*.

WOTTON (Dr William), a very learned divine and writer, was the son of Mr Henry Wotton, B. D. rector of Wrentham, in Suffolk, where he was born in 1666. He was educated by his father, a gentleman well skilled in the learned languages; under whom he made such amazing proficiency, that at five years of age he could render several chapters in the gospels out of Latin and Greek, and many psalms in Hebrew into his mother tongue. When he was very young, he remembered the whole of almost every discourse he had heard, and often surprised a preacher by repeating his sermon to him. He was admitted into Catharine-hall in Cambridge some months before he was ten years old; when the progress he made in learning in that university engaged Dr Duport, then master of Magdalen college, and dean of Peterborough, to write an elegant copy of Latin verses in his praise. In 1679 he took the degree of bachelor of arts when he was but twelve years and five months old; and the winter following he was invited to London by Dr Gilbert Burnet, then preacher at the Rolls, who introduced him to most of the learned men in this city, and particularly to Dr William Lloyd, bishop of St Asaph; to whom he recommended himself by repeating to him one of his sermons, as Dr Burnet had engaged he should. In 1691 he commenced bachelor of divinity. The same year bishop Lloyd gave him the sinecure of Llandrillo, in Denbighshire. He was afterwards made chaplain to the earl of Nottingham, then secretary of state, who presented him to the rectory of Middleton Keynes, in Bucks, and to whom he dedicated his *Reflections upon ancient and modern Learning*. In 1705, bishop Burnet gave him a prebend in the church of Salisbury; and in 1707, archbishop Tenison presented him with the degree of doctor of divinity: but in 1714, the difficulties he laboured under with respect to his private fortune, obliged him to retire into South Wales, where he was treated with great kindness and humanity by the gentlemen of that country; and wrote there the "*Memoirs of the Cathedral Churches of St David's and of Landaff*," and his "*Miscellaneous Discourses relating to the Traditions and Usages of the Scribes and Pharisees*;" which were afterwards printed. He died in 1726. This great man was remarkable for his humanity and friendliness of temper; the narrowness of a party-spirit never broke in upon any of his friendships; and his time and abilities were at the service of any person who was making advances in real learning. He wrote, besides the

Vol. X.

1

above works, 1. *A History of Rome*. 2. *A Defence of his Reflections upon ancient and modern Learning*. 3. *A Discourse concerning the Languages of Babel*. 4. *Advice to a young Student, with a Method of Study for the first four Years; and other learned pieces*.

WOUNDS. See SURGERY, Part II. sect. i. ii.

WOUNDS, in farriery. See there, § xvv.

WRASSE, or old wife, in ichthyology. See LABRUS.

WREATH, in heraldry, a roll of fine linen or silk (like that of a Turkish turban), consisting of the colours borne in the escutcheon, placed in an achievement between the helmet and the crest, and immediately supporting the crest.

WRECK, or SHIPWRECK, the destruction of a ship by rocks or shallows at sea.

By the ancient common law, where any ship was lost at sea, and the goods or cargo were thrown upon the land, these goods, so wrecked, were adjudged to belong to the king: for it was held, that, by the loss of the ship, all property was gone out of the original owner. But this was undoubtedly adding sorrow to sorrow, and was consonant neither to reason nor humanity. Wherefore it was first ordained by king Henry I. that if any person escaped alive out of the ship it should be no wreck; and afterwards king Henry II. by his charter, declared, that if on the coasts of either England, Poitou, Oleron, or Gascony, any ship should be distressed, and either man or beast should escape or be found therein alive, the goods should remain to the owners, if they claimed them within three months; but otherwise should be esteemed a wreck, and should belong to the king, or other lord of the franchise. This was again confirmed with improvements by king Richard I.; who, in the second year of his reign, not only established these concessions, by ordaining that the owner, if he was shipwrecked and escaped, *omnes res suas liberas et quietas haberet*, but also, that if he perished, his children, or in default of them his brethren and sisters, should retain the property; and in default of brother or sister, then the goods should remain to the king (A). And the law, as laid down by Bracon in the reign of Henry III. seems still to have improved in its equity. For then, if not only a dog (for instance) escaped, by which the owner might be discovered, but if any certain mark were set on the goods, by which they might be known again, it was held to be no wreck. And this is certainly most agreeable to reason; the rational claim of the king being only founded upon this, that the true owner cannot be ascertained. Afterwards, in the statute of Westminster the first, the time of limitation of claims, given by the charter of Henry II. is extended to a year and a day, according to the usage of Normandy: and it enacts; that if a man, a dog, or a cat, escape alive, the vessel shall not be adjudged a wreck. These animals, as in Bracon, are only put for examples; for it is now held, that not only if any live thing escape, but if proof can be made of the property of any of the goods or lading which come to

Wounds

Wreck.

45 E

shore,

(A) In like manner Constantine the Great, finding that by the imperial law the revenue of wrecks was given to the prince's treasury or *fiscus*, restrained it by an edict (Cod. 11. 5. 1.), and ordered them to remain to the owners; adding this humane expostulation: "*Quod enim jus habet *fiscus* in aliena calamitate, ut de re tam luculosa com, indigne scietur?*"

Wreck.

shore, they shall not be forfeited as wreck. The statute further ordains, that the sheriff of the county shall be bound to keep the goods a year and a day (as in France for one year, agreeably to the maritime laws of Oleron, and in Holland for a year and a half), that if any man can prove a property in them, either in his own right or by right of representation, they shall be restored to him without delay; but if no such property be proved within that time, they then shall be the king's. If the goods are of a perishable nature, the sheriff may sell them, and the money shall be liable in their stead. This revenue of wrecks is frequently granted out to lords of manors as a royal franchise; and if any one be thus intitled to wrecks in his own land, and the king's goods are wrecked thereon, the king may claim them at any time, even after the year and day.

It is to be observed, that in order to constitute a legal wreck, the goods must come to land. If they continue at sea, the law distinguishes them by the barbarous and uncouth appellations of *jetfam*, *stotfam*, and *ligan*. *Jetfam* is where goods are cast into the sea, and there sink and remain under water: *stotfam* is where they continue swimming on the surface of the waves: *ligan* is where they are sunk in the sea, but tied to a cork or buoy, in order to be found again. These are also the king's, if no owner appears to claim them; but if any owner appears, he is intitled to recover the possession. For even if they be cast overboard, without any mark or buoy, in order to lighten the ship, the owner is not by this act of necessity construed to have renounced his property: much less can things *ligan* be supposed to be abandoned, since the owner has done all in his power to assert and retain his property. These three are therefore accounted so far a distinct thing from the former, that by the king's grant to a man of wrecks, things *jetfam*, *stotfam*, and *ligan* will not pass.

Wrecks, in their legal acceptance, are at present not very frequent: for if any goods come to land, it rarely happens, since the improvement of commerce, navigation, and correspondence, that the owner is not able to assert his property within the year and day limited by law. And in order to preserve this property entire for him, and if possible to prevent wrecks at all, our laws have made many very humane regulations; in a spirit quite opposite to those savage laws, which formerly prevailed in all the northern regions of Europe, and a few years ago were still said to subsist on the coasts of the Baltic sea, permitting the inhabitants to seize on whatever they could get as lawful prize; or, as an author of their own expresses it, "*in naufragorum miseria et calamitate tanquam vultures ad prædam currere.*" For by the statute 27 Edw. III. c. 13. if any ship be lost on the shore, and the goods come to land (which cannot, says the statute, be called *wreck*), they shall be presently delivered to the merchants, paying only a reasonable reward to those that saved and preserved them, which is intitled *salvage*. Also by the common law, if any persons (other than the sheriff) take any goods so cast on shore, which are not legal wreck, the owners might have a commission to inquire and find them out, and compel them to make restitution. And by statute 12 Ann. §. 2. c. 18. confirmed by 4 Geo. I. c. 12. in order to

assist the distressed, and prevent the scandalous illegal practices on some of our sea coasts (too similar to those on the Baltic), it is enacted, that all head-officers and others of towns near the sea, shall, upon application made to them, summon as many hands as are necessary, and send them to the relief of any ship in distress, on forfeiture of 100*l.* and in case of assistance given, salvage shall be paid by the owners, to be assessed by three neighbouring justices. All persons that secret any goods shall forfeit their treble value: and if they wilfully do any act whereby the ship is lost or destroyed, by making holes in her, stealing her pumps, or otherwise, they are guilty of felony, without benefit of clergy. Lastly, by the statute 26 Geo. II. c. 19. plundering any vessel, either in distress or wrecked, and whether any living creature be on board or not (for whether wreck or otherwise, it is clearly not the property of the populace), such plundering, or preventing the escape of any person that endeavours to save his life, or wounding him with intent to destroy him, or putting out false lights in order to bring any vessel into danger, are all declared to be capital felonies; in like manner as the destroying of trees, steeples, or other stated sea-marks, is punished by the statute 8 Eliz. c. 13. with a forfeiture of 100*l.* or outlawry. Moreover, by the statute of Geo. II. pilfering any goods cast ashore is declared to be petty larceny; and many other salutary regulations are made, for the more effectually preserving ships of any nation in distress.

By the civil law, to destroy persons shipwrecked, or prevent their saving the ship, is capital. And to steal even a plank from a vessel in distress, or wrecked, makes the party liable to answer for the whole ship and cargo. The laws also of the Wisigoths, and the most early Neapolitan constitutions, punished with the utmost severity all those who neglected to assist any ship in distress, or plundered any goods cast on shore.

WREN, in ornithology. See MOTACILLA.

WREN (Sir Christopher), a great philosopher, and one of the most learned and most eminent architects of his age, was the son of Christopher Wren dean of Windsor, and was born in 1632. He studied at Wadham college in Oxford; where he took the degree of master of arts in 1653, and was chosen fellow of All-Souls college there. When very young, he discovered a surprising genius for the mathematics; in which science he made great advances before he was sixteen years old. In 1657, he was made professor of astronomy at Gresham college, London; which he resigned in 1660, on his being chosen to the Savilian professorship of astronomy in Oxford: he was the next year created doctor of laws, and in 1663 was elected fellow of the Royal Society. He was one of the commissioners for the reparation of St Paul's; and in 1665 travelled into France, to examine the most beautiful edifices there, when he made many curious observations. At his return to England, he drew a noble plan for rebuilding the city of London after the fire, which he presented to parliament; and upon the decease of Sir John Denham in 1668, was made surveyor-general of his majesty's works; and from this time had the direction of a great number of public edifices, by which he acquired the highest reputation. He built the magnificent theatre at Oxford:

Wreck.
Wren.

estling St Paul's cathedral, the churches of St Stephen Walbrook, and St Mary-le-Bow, the Monument, the modern part of the palace of Hampton-Court, Chelsea college, one of the wings of Greenwich hospital, and many other beautiful edifices. He was president of the Royal Society, one of the commissioners of Chelsea college, and twice member of parliament, first for Plymouth in Devonshire, and then for Melcomb Regis in the same county; but in 1718 was removed from his place of surveyor-general. He died in 1723, and was interred in the vault under St Paul's.

This great man also distinguished himself by many curious inventions and discoveries in natural philosophy; and, among many others, contrived an instrument for measuring the quantity of rain that falls on any space of land for a year; invented many ways of making astronomical observations more accurate and easy; and was the first author of the anatomical experiment of injecting liquors into the veins of animals, &c. He translated into Latin Mr Oughtred's *Horologigraphica Geometrica*; and wrote a Survey of the cathedral church of Salisbury, and other pieces. Since his death his posthumous works and draughts have been published by his son.

WRESTLING, a kind of combat or engagement between two persons unarmed, body to body, to prove their strength and dexterity, and try which can throw his opponent to the ground.

Wrestling is an exercise of very great antiquity and fame. It was in use in the heroic age; witness Hercules, who wrestled with Antaeus.

It continued a long time in the highest repute, and had considerable rewards and honours assigned it at the Olympic games. It was the custom for the Athletæ to anoint their bodies with oil, to give the less hold to their antagonist.

Lycurgus ordered the Spartan maids to wrestle in public, quite naked, in order, as it is observed, to break them of their too much delicacy and nice-ness, to make them appear more robust, and to familiarize the people, &c. to such nudities.

WRIST, in anatomy. See there n° 53.

WRIT, in law, signifies, in general, the king's precept in writing under seal, issuing out of some court, directed to the sheriff, or other officer, and commanding something to be done in relation to a suit or action, or giving commission to have the same done. And, according to Fitzherbert, a writ is said to be a formal letter of the king in parchment, sealed with his seal, and directed to some judge, officer, or minister, &c. at the suit of a subject, for the cause briefly expressed, which is to be determined in the proper court according to law.

WRITS, in civil actions, are either original or judicial: original, are such as are issued out of the court of chancery for the summoning of a defendant to appear, and are granted before the suit is commenced, in order to begin the same; and judicial writs issue out of the court where the original is returned, after the suit is begun. See **PROCESS**.

The original writ is the foundation of the suit. See **SUIT**.

When a person hath received an injury, and thinks it worth his while to demand a satisfaction for it, he is to consider with himself, or take advice, what

redress the law has given for that injury; and thereupon is to make application or suit to the crown, the fountain of all justice, for that particular specific remedy which he is determined or advised to pursue. As for money due on bond, an action of debt; for goods detained without force, an action of *detinue or trover*; or, if taken with force, an action of *trespass vi et armis*; or, to try the title of lands, a writ of entry or action of trespass in ejectment; or, for any consequential injury received, a special action on the case. To this end he is to sue out, or purchase by paying the stated fees, an *original* or original writ, from the court of chancery, which is the *officina justitie*, the shop or mint of justice, wherein all the king's writs are framed. It is a mandatory letter from the king in parchment, sealed with his great seal, and directed to the sheriff of the county wherein the injury is committed, or supposed so to be, requiring him to command the wrong-doer or party accused, either to do justice to the complainant, or else to appear in court, and answer the accusation against him. Whatever the sheriff does in pursuance of this writ, he must return or certify to the court of common pleas, together with the writ itself: which is the foundation of the jurisdiction of that court, being the king's warrant for the judges to proceed to the determination of the cause. For it was a maxim introduced by the Normans, that there should be no proceedings in common-pleas before the king's justices without his original writ; because they held it unfit that those justices, being only the substitutes of the crown, should take cognizance of any thing but what was thus expressly referred to their judgment. However, in small actions, below the value of forty shillings, which are brought in the court-baron or county court, no royal writ is necessary; but the foundation of such suits continue to be (as in the times of the Saxons) not by original writ, but by plaint; that is, by a private memorial tendered in open court to the judge, wherein the party injured sets forth his cause of action: and the judge is bound of common right to administer justice therein, without any special mandate from the king. Now indeed even the royal writs are held to be demandable of common right, on paying the usual fees: for any delay in the granting them, or setting an unusual or exorbitant price upon them, would be a breach of magna carta, c. 29. "nulli vendemus, nulli negabimus, aut differemus justitiam vel rectum."

Original writs are either optional or peremptory; or, in the language of our law, they are either a *præcipe*, or a *si te fecerit securum*. The *præcipe* is in the alternative, commanding the defendant to do the thing required, or show the reason wherefore he hath not done it. The use of this writ is where something certain is demanded by the plaintiff, which is in the power of the defendant himself to perform; as, to restore the possession of land, to pay a certain liquidated debt, to perform a specific covenant, to render an account, and the like: in all which cases the writ is drawn up in the form of a *præcipe* or command, to do thus, or show cause to the contrary; giving the defendant his choice, to redress the injury or stand the suit. The other species of original writs is called a *si fecerit te securum*, from the words of the writ; which directs the sheriff to cause the defendant to appear in court,

Writing,
Wurttem-
burg.

without any option given him, provided the plaintiff gives the sheriff security effectually to prosecute his claim. This writ is in use where nothing is specifically demanded, but only a satisfaction in general; to obtain which, and minister complete address, the intervention of some judicature is necessary. Such are writs of trespass, or on the case, wherein no debt or other specific thing is used for in certain, but only damages to be assailed by a jury. For this end the defendant is immediately called upon to appear in court, provided the plaintiff gives good security of prosecuting his claim. Both species of writs are tested, or witnessed, in the king's own name; "witnesses ourself at Westminster," or wherever the chancery may be held.

The security here spoken of, to be given by the plaintiff for prosecuting his claim, is common to both writs, though it gives denomination only to the latter. The whole of it is at present become a mere matter of form; and John Doe and Richard Roe are always returned as the standing pledges for this purpose.—The ancient use of them was to answer for the plaintiff, who in case he brought an action without cause, or failed in the prosecution of it when brought, was liable to an amercement from the crown for raising a false accusation; and so the form of the judgment still is. In like manner, as by the Gothic constitutions no person was permitted to lay a complaint against another, *nisi sub scriptura aut specificatione trium testium, quod actionem vellet persequi*: and, as by the laws of Sancho I, king of Portugal, damages were given against a plaintiff who prosecuted a groundless action.

The day on which the defendant is ordered to appear in court, and on which the sheriff is to bring in the writ, and report how far he has obeyed it, is called the *return of the writ*; it being then returned by him to the king's justices at Westminster. And it is always made returnable at the distance of at least 15 days from the date or teste, that the defendant may have time to come up to Westminster, even from the most remote parts of the kingdom; and upon some day in one of the four terms, in which the court sits for the dispatch of business.

WRITING, the art or act of signifying and conveying our ideas to others, by letters or characters visible to the eye. See COMPOSITION, GRAMMAR, and LANGUAGE.

WURTEMBERG, or WIRTEMBERG, a sovereign duchy of Germany, in Suabia; bounded on the north by Franconia, the archbishopric of Mentz, and the palatinate of the Rhine; on the east by the county of Oeting, the marquise of Burgau, and the territory of Ulm; on the south by the principality of Hohen-Zollern, Furstburg, and the marquise of Hohenburg; and on the west by the palatinate of the Rhine, the marquise of Baden, and the Black Forest. It is 65 miles in length, and as much in breadth, and the river Neckar runs almost through the middle of it from S. to N. Though there are many mountains and woods, yet it is one of the most populous and fertile countries in Germany, producing plenty of pastures, corn, fruits, and a great deal of wine towards the confines of the palatinate. There are also mines, and salt springs, with plenty of game and fish. It

contains 645 villages, 88 towns, and 26 cities, of which Stuttgart is the capital.

WURTSBURG, the bishopric of a large country of Germany, comprehending the principal part of Franconia. It is bounded by the county of Henneburg, the duchy of Coburg, the abbey of Fulda, the archbishopric of Mentz, the marquise of Anspach, the bishopric of Bamberg, and the county of Wertheim; being about 65 miles in length, and 50 in breadth, and divided into 50 bailiwicks. The soil is very fertile, and produces more corn and wine than the inhabitants consume. The territories of the bishop comprehend above 400 towns and villages, of which he is sovereign, being one of the greatest ecclesiastical princes of the empire.

WURTZBURG, a large and handsome city of Germany, and one of the principal in the circle of Franconia. It is defended with good fortifications, and has a magnificent palace. There is a handsome hospital, in which are generally 400 poor men and women. The castle is at a small distance from the city, and commands it, as it stands upon an eminence. It communicates with the city by a stone-bridge, on which are 12 statues, representing as many saints.—The arsenal and the cellars of the bishops deserve the attention of the curious. There is also an university, founded in 1403. It is seated on the river Maine, E. Long. 10. 5. N. Lat. 49. 44.

WYAT (Sir Thomas), an accomplished writer in the reign of Henry VIII. was the son of Sir Henry Wyatt of Allington castle in Kent. He was born in the year 1503, and educated at St John's college, Cambridge. He then visited foreign countries, and probably spent some years abroad; for, at his return to England, he was exceedingly accomplished, and perfectly acquainted with the languages, and polite literature of those times. King Henry VIII. charmed with his abilities, and delighted with his vivacity and wit, immediately took him into favour, honoured him with knighthood, gave him lands, and employed him in several embassies. Nevertheless Wyatt fell into disgrace, and was twice imprisoned. It is evident, however, that he regained the favour and confidence of the king; for he was afterwards sent ambassador to the emperor, and died in the execution of his majesty's commission. The nature of this commission is differently related. Be it what it might, it proved fatal. Riding post in the heat of summer, he was attacked by a violent fever, and died at Shirebourn, in Dorsetshire, in 1541. Sir Thomas Wyatt was cotemporary with Henry Howard, earl of Surrey, and his intimate friend, with whom he shares the honour of polishing our language, and of introducing the numbers used by the Italian poets. Camden calls him *splendide doctus*; and Acliam says, he was one of the best translators of the Latin poets. His oration on his trial (lately published in Miscellaneous Antiquities) shows him to have been a man of considerable ability, and an orator. Leland published a collection of elegies on his death, under the title *Nenia*; which Cibber, in his *Lives of the Poets*, mistakes for a collection of his works. To this book there is prefixed a portrait of Sir Thomas, with a long beard, from a painting of Holbein. His Songs and Poems, among the sonnets of the earl of Surrey, were printed in 1565; 1587, 8vo.

WYCHER-

Wycherley.

WYCHERLEY (William), an eminent English comic poet, was born about 1640. A little before the restoration of king Charles II. he became a gentleman commoner of Queen's-college Oxford, where he was reconciled by Dr Barlow to the protestant religion, which he had a little before abandoned in his travels. He afterward entered himself in the Middle-temple, but soon quitted the study of the law for pursuits more agreeable to his own genius, as well as to the taste of the age: Upon writing his first play, intitled, *Love in a Wood, or St James's Park*, which was acted in 1672, he became acquainted with several of the celebrated with both of the court and town, and likewise with the duchess of Cleveland. Some time after appeared his comedies, called *The Gentleman-Dancing-Master*, his *Plain Dealer*, and his *Country Wife*; all which were acted with applause. George duke of Buckingham had a very high esteem for him, and bestowed on him several advantageous posts.—King Charles also showed him signal marks of favour; and once gave him a proof of his esteem, which perhaps never any sovereign prince before had given to a private gentleman. Mr Wycherley being ill of a fever, at his lodgings in Bow-street, the king did him the honour of a visit. Finding him extremely weakened, he commanded him to take a journey to the south of France, and assured him, at the same time, that he would order him 500*l.* to defray the charges of the journey. Mr Wycherley accordingly went into France; and having spent the winter there, returned to England entirely restored to his former vigour. The king, shortly after his arrival, told him, that he had a son, who he was resolved should be educated like the son of a king, and that he could not choose a more proper man for his governor than Mr Wycherley; for which service 1500*l.* per annum should be settled upon him.

Mr Wycherley, however, such is the uncertain fate of all human affairs, lost the favour of the king by the following means: Immediately after he had received the gracious offer above mentioned, he went down to Tunbridge, where, walking one day upon the Wells-walk, with his friend Mr Fairbeard of Gray's Inn, just as he came up to the bookfeller's shop, the countess of Drogheda, a young widow, rich, noble, and beautiful, came there to inquire for *The Plain Dealer*; "Madam," says Mr Fairbeard, "since you are for the Plain Dealer, there he is for you;" pushing Mr Wycherley towards her. "Yes," says Mr Wycherley, "this lady can bear plain dealing; for she appears to be so accomplished, that what would be a compliment to others, would be plain dealing to her." "No, truly, Sir," said the countess, "I am not without my faults, any more than the rest of my sex; and yet, notwithstanding, I love plain dealing, and am never more fond of it than when it tells me of them." "Then, madam," says Mr Fairbeard, "you and the Plain Dealer seem designed by Heaven for each other."—In short, Mr Wycherley walked a turn or two with the countess, waited upon her home, visited her daily at her lodgings while she laid at Tunbridge, and at her lodgings in Hatton-garden after she went to London; where in a little time he married her, without acquainting the king. By this step, which was looked upon as a contempt of his majesty's orders, he

forfeited the royal favours. The countess of Drogheda first led her whole fortune upon him; but his title being disputed after her death, he was so reduced by the expences of the law, and other incumbrances, as to be unable to satisfy the impatience of his creditors, who threw him into prison; and the bookfeller who printed his Plain Dealer, by which he got almost as much money as the other gained reputation, was so ungrateful as to refuse to lend him 20*l.* in his extreme necessity. In that confinement he languished seven years; but at length king James going to see the above play, was so charmed with it, that he gave immediate orders for the payment of his debts, and even granted him a pension of 200*l.* per annum. But that prince's bountiful intentions were in a great measure defeated merely through Mr Wycherley's modesty, he being ashamed to tell the earl of Mulgrave, whom the king had sent to demand it, a true state of his debts. He laboured under the weight of these difficulties till his father died, who left him 600*l.* a-year. But this estate was under uneasy limitations, he being only a tenant for life, and not being allowed to raise any money for the payment of his debts. However, he took a method of doing it which few suspected to be his choice; and this was making a jointure. He had often declared, that he was resolved to die married, though he could not bear the thoughts of living in that state again: accordingly, just at the eve of his death, he married a young gentlewoman with 1500*l.* fortune, part of which he applied to the uses he wanted it for. Eleven days after the celebration of these nuptials, in December 1715, he died, and was interred in the vault of Covent-garden church.

Besides his plays above mentioned, he published a volume of poems in folio. In 1728 his posthumous works in prose and verse were published by Mr Theobald. He was intimate with Mr Pope, Mr Gay, and the other great poets of his time.

WYNDHAM (Sir William), descended of an ancient family, was born about the year 1687, and succeeded young to the title and estate of his father. On his return from his travels, he was chosen member for the county of Somerset; in which station he served in the three last parliaments of queen Anne, and as long as he lived: after the change of the ministry in 1710, he was appointed secretary at war; and in 1713, was raised to be chancellor of the exchequer. Upon the breach between the earl of Oxford and lord Bolingbroke, he adhered to the interests of the latter. He was removed from his employment on the accession of George I. and falling under suspicion on the breaking out of the rebellion in 1715, was apprehended. He made his escape; a reward was published for apprehending him; he surrendered, was committed to the Tower, but never brought to a trial. After he regained his liberty, he continued in opposition to the several administrations under which he lived; and died in 1740.

WYKEHAM (William of). See WILLIAM.

WYE, a river of Wales, which rising on the confines of Cardiganhire, and running south-east, divides the counties of Radnor and Brecknock; then crossing Herefordshire, it runs south and falls into the mouth of the Severn at Chepstow.

Wyc.

X.

X
Xebec.

X, or **x**, is the 22d letter of our alphabet, and a double consonant. It was not used by the Hebrews or ancient Greeks; for as it is a compound letter, the ancients, who used great simplicity in their writings, made use of, and expressed this letter by its component letters *cs*. Neither have the Italians this letter, but express it by *ss*. **X** begins no word in our language but such as are of Greek original; and is in few others but what are of Latin derivation; as *perplex*, *reflexion*, *defluxion*, &c. We often express this sound by single letters, as *ch*, in *backs*, *necks*; by *ks*, in *books*, *breaks*; by *cc*, in *access*, *accident*; by *ct*, in *action*, *unction*, &c. The English and French pronounce it like *cs* or *ks*; the Spaniards like *c* before *a*, viz. *Alexandro*, as if it were *Alecandro*. In numerals it expresseth 10, whence in old Roman manuscripts it is used for *denarius*; and as such seems to be made of two *V*'s placed one over the other. When a dash is added over it, thus **X̄**, it signifies 10,000.

XANTHIUM, *Ditch Bur*; a genus of the pentandria order, belonging to the monœcia class of plants. There are three species; of which the most remarkable is the strumarium, or lesser burdock, growing naturally on dunghills in many places of Britain. The leaves are bitter and astringent. A decoction of the whole plant affords a showy yellow colour, but it is better if only the flowers are used. Horses and goats eat it; cows, sheep, and swine refuse it.

XANTHOXYLUM. See **ZANTHOXYLUM**.

XEBEC, a small three-masted vessel, navigated in the Mediterranean Sea, and on the coasts of Spain, Portugal, and Barbary. See **PLATE CCLXV**.

The sails of the xebec are in general similar to those of the poleacre, but the hull is extremely different from that and almost every other vessel. It is furnished with a strong prow; and the extremity of the stern, which is nothing more than a sort of railed platform or gallery, projects further behind the counter and buttock than that of any European ship.

Being generally equipped as a corsair, the xebec is constructed with a narrow floor, to be more swift in pursuit of the enemy; and of a great breadth, to enable her to carry a great force of sail for this purpose without danger of overturning. As these vessels are usually very low built, their decks are formed with a great convexity from the middle of their breadth towards the sides, in order to carry off the water which falls aboard more readily by their scuppers. But as this extreme convexity would render it very difficult to walk thereon at sea, particularly when the vessel rocks by the agitation of the waves, there is a platform of grating extending along the deck from the sides of the vessel towards the middle, whereon the crew may walk dry-footed whilst the water is conveyed through the grating to the scuppers.

When a xebec is equipped for war, she is occasion-

ally navigated in three different methods, according to the force or direction of the wind.

Thus, when the wind is fair, and nearly astern, it is usual to extend square-sails upon the main-mast; and indeed frequently on the fore-mast: and as those sails are rarely used in a scant wind, they are of an extraordinary breadth.

When the wind is unfavourable to the course, and yet continues moderate, the square yards and sails are removed from the masts, and laid by, in order to make way for the large lateen yards and sails, which soon after assume their place: but if the foul wind increases to a storm, these latter are also lowered down and displaced; and small lateen yards with proportional sails are extended on all the masts.

The xebecs, which are generally armed as vessels of war by the Algerines, mount from 16 to 24 cannon, and carry from 300 to 450 men, two thirds of whom are generally soldiers.

By the very complicated and inconvenient method of working these vessels, it will be readily believed what one of their captains of Algiers acquainted Mr Falconer, viz. That the crew of every xebec has at least the labour of three square-rigged ships, wherein the standing sails are calculated to answer every situation of the wind.

XENOCRATES, one of the most illustrious philosophers of ancient Greece, was born in Chalcedon, and became early a disciple of Plato. He studied under this great master at the same time with Aristotle, but was not possessed of the same talents; he wanting a spur, and the other a bridle. However, if Xenocrates, by the heaviness of his genius, was greatly inferior to Aristotle, he excelled him very much in practical philosophy. There was something extraordinary in the sagacity of his morals. He was absolute master of his passions; and was not fond of pleasure, riches, or applause. So great was his reputation for sincerity and probity, that he was the only person whom the magistrates of Athens dispensed from confirming his testimony with an oath. There was nothing graceful in the behaviour of Xenocrates, but a seriousness and severity were always seen in his deportment; for which reason Plato frequently exhorted him to sacrifice to the Graces. Notwithstanding this severe cast of mind, he yet was extremely compassionate. He was fond of the mathematics; and permitted none of his scholar's to be ignorant of them. It is surprising that a philosopher of so much merit should have been so ill treated by the Athenians, as to be sold because he could not pay the poll-tax laid on foreigners. Demetrius Phalereus bought Xenocrates, set him immediately at liberty, and paid the Athenians the debt. Xenocrates died 314 B. C. at about 90 years of age, by accidentally striking his forehead against a kettle in the night. He composed, at Alexander's

Xebec.
Xenocrates.

ander's desire, a Treatise on the Art of Reigning; fix books on Nature; fix books on Philosophy; one on Riches, &c. but none of these works have been handed down to us. Our philosopher's theology was but poor stuff: Cicero refutes him in the first book of the Nature of the Gods.

XENOPHANES, a Greek philosopher, born in Colophon, was, say some authors, the disciple of Archelaus; according to which he must have been contemporary with Socrates. Others relate, that he taught himself all he knew, and that he lived at the same time with Anaximander. By this account he must have flourished before Socrates, and about the 60th Olympiad, as Diogenes Laertius affirms. He wrote several poems on philosophical subjects; as also a great many on the foundation of Colophon, and on that of the colony of Elea. His opinion with regard to the nature of God does not differ much from that of Spinoza. He wrote against Homer and Hesiod. When he saw the Egyptians pour forth lamentations during their festivals, he thus advised them: "If the objects of your worship are Gods, do not weep; if they are men, offer not sacrifices to them." He was banished from his country, withdrew to Sicily, and lived in Zanche and Catana. He founded the Eleatic sect. The answer Xenophanes made to a man, with whom he had refused to play at dice, is highly worthy of a philosopher. This man calling him a coward, "Yes," (replied he) I am excessively so with regard to all shameful actions.

XENOPHON, a celebrated general, philosopher, and historian, was born at Athens, and became early a disciple of Socrates, who is said by Strabo to have saved his life in battle. About the 50th year of his age he engaged in the expedition of Cyrus, and accomplished his immortal retreat in the space of 15 months. The jealousy of the Athenians banished him from his native city for engaging in the service of Sparta and Cyrus. On his return therefore he retired to Scillus, a town of Elis, where he built a temple to Diana, which he mentions in his Epistles, and devoted his leisure to philosophy and rural sports. But commotions arising in that country, he removed to Corinth, where he is supposed to have written his Grecian History, and to have died at the age of 90, in the year 360 before Christ. By his wife Philefia he had two sons, Diodorus and Gryllus. The latter rendered himself immortal by killing Epaminondas in the famous battle of Mantinea, but perished in that exploit, which his father lived to record. The best editions of his works are those of Franckfort in 1674, and of Oxford, in Greek and Latin, in 1703, 5 vols, 8vo. Separately have been published his *Cyropædia*, Oxon 1727, 4to, and 1736, 8vo. *Cyri Anabasis*, Oxon 1735, 4to, and 1747, 8vo. *Memorabilia Socratis*, Oxon 1741, 8vo. His *Cyropædia* has been admirably translated into English by Mr Spelman.

XENOPHON the Younger, a Greek writer, so called to distinguish him from the celebrated Xenophon, was born at Ephesus, and lived, according to some authors, before Heliodorus, that is, about the beginning of the 4th century. He is only known by his *Ephesiaca*, a Greek romance, in five books, which is effeminate, and contains the amours or adventures of Abracomes and Authia. This romance was printed at London, in

Greek and Latin, in 1724, 4to.

XERXES I. the fifth king of Persia, memorable for the vast army he is said to have carried into the field against Leonidas king of Sparta; consisting, according to some historians, of 800,000 men, while others make it amount to 3,000,000, exclusive of attendants. The fleet that attended this prodigious land force is likewise made to consist of 2000 sail; and all the success they met with was the taking and burning the city of Athens; for the army was shamefully repulsed near the Straights of Thermopylæ by Leonidas, with only 4000 chosen Spartans, and the fleet was dispersed and partly destroyed by Themistocles at the Straights of Salamis, who had only 380 sail under his command. Xerxes was assassinated by Artabanus, chief captain of his guards, and his distinguished favourite.

XIMENES (Francis), a justly celebrated cardinal, bishop of Toledo, and prime minister of Spain, was born at Torrelaguna, in Old Castile, in 1437, and studied at Alcalá and Salamanca. He then went to Rome; and being robbed on the road, brought nothing back but a bull for obtaining the first vacant prebend: but the archbishop of Toledo refused it him, and threw him in prison. Being at length restored to liberty, he obtained a benefice in the diocese of Sigüenza, where cardinal Gonzales de Mendoza, who was the bishop, made him his grand vicar. Ximenes some time after entered among the Franciscans of Toledo; but being there troubled with visits, he retired to a solitude named *Casafiel*, and applied himself to the study of divinity and the Oriental tongues. At his return to Toledo, queen Isabella of Castile chose him for her confessor, and afterwards nominated him archbishop of Toledo; which, next to the papacy, is the richest dignity in the church of Rome. "This honour (says Dr Robertson) he declined with a firmness, which nothing but the authoritative injunction of the pope was able to overcome. Nor did this height of promotion change his manners. Though obliged to display in public that magnificence which became his station, he himself retained his monastic severity. Under his pontifical robes he constantly wore the coarse frock of St Francis, the rents of which he used to patch with his own hands. He at no time used linen; but was commonly clad in hair-cloth. He slept always in his habit, most frequently on the floor, or on boards, and rarely in a bed. He did not taste any of the delicacies which appeared at his table, but satisfied himself with that simple diet which the rule of his order prescribed. Notwithstanding these peculiarities, so opposite to the manners of the world, he possessed a thorough knowledge of its affairs, and discovered talents for business which rendered the same of his wisdom equal to that of his sanctity." His first care was to provide for the necessities of the poor; to visit the churches and hospitals; to purge his diocese of usurers and places of debauchery; to degrade corrupt judges, and place in their room persons whom he knew to be distinguished by their probity and disinterestedness. He erected a famous university at Alcalá; and in 1499 founded the college of St Ildephonso. Three years after he undertook the Polyglot Bible; and for that purpose sent for many learned men to come to him at Toledo, purchased seven copies in Hebrew for 4000 crowns, and gave a great price for Latin and Greek manuscripts. At this

Ximenes.

Ximenes.

Bible they laboured above 12 years. It contains the Hebrew text of the Bible; the version of the Septuagint, with a literal translation; that of St. Jerom, and the Chaldee paraphrases of Onkelos; and Ximenes added to it a dictionary of the Hebrew and Chaldee words contained in the Bible. This work is called *Ximenes's Polyglot*. In 1507 pope Julius II. gave him the cardinal's hat, and king Ferdinand the Catholic entrusted him with the administration of affairs. Cardinal Ximenes was from this moment the soul of every thing that passed in Spain. He distinguished himself at the beginning of his ministry by discharging the people from the burdensome tax called *acavale*, which had been continued on account of the war against Granada; and laboured with such zeal and success in the conversion of the Mahometans, that he made 3000 converts, among whom was a prince of the blood of the kings of Granada. This great multitude he baptized in a spacious square; where having made them bring all the books of the Koran, he had them publicly burnt. The day in which this was performed is annually solemnized as a festival in Spain. In 1509 cardinal Ximenes extended the dominions of Ferdinand, by taking the city of Oran in the kingdom of Algiers. He undertook this conquest at his own expence, and marched in person at the head of the Spanish army clothed in his pontifical ornaments, and accompanied by a great number of ecclesiastics and monks. Some time after, foreseeing an extraordinary scarcity, he erected public granaries at Toledo, Alcalá, and Torrelaguna, and had them filled with corn at his own expence; which gained the people's hearts to such a degree, that to preserve the memory of this noble action they had an elogium upon it cut on marble, in the hall of the senate-house at Toledo, and in the market-place. King Ferdinand dying in 1516, left cardinal Ximenes regent of his dominions; and the archduke Charles, who was afterwards the emperor Charles V. confirmed that nomination. The cardinal immediately made a reform of the officers of the supreme council and of the court, and put a stop to the oppression of the grandees. He vindicated the rights of the people against the nobility; and as by the feudal constitution the military power was lodged in the hands of the nobles, and men of inferior condition were called into the field only as their vassals, a king with scanty revenues depended on them in all his operations. It was with their forces he attacked his enemies, and with them he defended his own kingdom; and while at the head of troops attached only to their own lords, and accustomed to obey no other command, his authority was precarious, and his efforts feeble. From this state Ximenes resolved to deliver the crown; and issued a proclamation, commanding every city in Castile to enroll a certain number of its burgesses, and teach them military discipline, he himself engaging to provide officers to command them at the public expence. This was vigorously opposed by the nobles; but by his integrity and superior address he carried his point. He then endeavoured to diminish the possessions of the nobility, by reclaiming all the crown lands, and putting a stop to the pensions granted by the late king Ferdinand. This addition made to the revenues enabled him to discharge all the debts of Ferdinand, and to establish magazines of warlike stores. The nobles,

alarmed at these repeated attacks, uttered loud complaints; but before they proceeded to extremities, appointed some grandees of the first rank to examine the powers, in consequence of which he exercised acts of such high authority. Ximenes received them with cold civility, produced the testament of Ferdinand, by which he was appointed regent, together with the ratification of that deed by Charles. To both these they objected; and he endeavoured to establish their validity. As the conversation grew warm, he led them insensibly to a balcony, from which they had a view of a large body of troops under arms, and of a formidable train of artillery. "Behold (says he, pointing to these, and raising his voice) the powers which I have received from his Catholic majesty. With these I govern Castile; and with these I will govern it, till the king, your master and mine, takes possession of his kingdom." A declaration so bold and haughty silenced them, and astonished their associates. They saw that he was prepared for his defence, and laid aside all thoughts of a general confederacy against his administration. He also founded two magnificent monasteries; one for the pious education of a great number of ladies of quality, who had no fortunes, and the other an asylum for poor girls. He was at great expence in embellishing his native town Torrelaguna, with a fountain of running water, which he caused to be brought through rocks and mountains, and with several other public works. At length, from the repeated entreaties of Ximenes, and the impatient murmurs of the Spanish ministry, Chas. V. embarked and landed in Spain, accompanied by his favourites. Ximenes, who considered the presence of the king as the greatest blessing to his dominions, was advancing to the coast to meet him; but at Bos Equilos was seized with a violent disorder, which his followers considered as the effects of poison, but could not agree whether the crime ought to be imputed to the hatred of the Spanish nobles, or to the malice of the Flemish courtiers. This accident obliging Ximenes to stop, he wrote to the king, and with his usual boldness advised him to dismiss all the strangers in his train, whose number and credit already gave offence to the Spaniards, and earnestly desired to have an interview with him, that he might inform him of the state of the nation, and the temper of his subjects. To prevent this, not only the Flemings, but the Spanish grandees, employed all their address to keep Charles at a distance from Aranda, the place to which the cardinal had removed. His advice was now slighted and despised. Ximenes, conscious of his own integrity and merit, expected a more grateful return from a prince, to whom he delivered a kingdom more flourishing than it had been in any former age, and a more extensive authority than the most illustrious of his ancestors had ever possessed; and lamented the fate of his country, about to be ruined by the rapaciousness and insolence of foreign favourites. While his mind was agitated by these passions, he received a letter from the king; in which, after a few cold and formal expressions of regard, he was allowed to retire to his diocese; and he expired a few hours after reading it, in 1517, in the 81st year of his age.

This famous cardinal ought not to be confounded with

Roderic XIMENES, archbishop of Toledo, in the

ICHTHYOLOGY.

Fig. 4.

Fig. 5.

13th century, who wrote a History of Spain in nine books; nor with several other Spanish writers of the name of *Ximenes*.

XIPHIAS, the SWORD-FISH; a genus belonging to the order of apodes. The upper jaw terminates in a long sword-shaped rostrum, from which it is called the *sword-fish*: there are no teeth in the mouth; the gill-membrane has eight rays; and the body is somewhat cylindrical. There is but one species, viz. the gladius, found in the European ocean.

This fish sometimes frequents our coasts, but is much more common in the Mediterranean sea, especially in the part that separates Italy from Sicily, which has been long celebrated for it: the promontory Pelorus, now Capo di Faro, was a place noted for the resort of the xiphias, and possibly the station of the speculators, or the persons who watched and gave notice of the approach of the fish.

The ancient method of taking them is particularly described by Strabo, and agrees exactly with that practised by the moderns.

A man ascends one of the cliffs that overhangs the sea: as soon as he spies the fish, he gives notice, either by his voice or by signs, of the course it takes. Another, that is stationed in a boat, climbs up the mast, and on seeing the sword-fish, directs the rowers towards it. As soon as he thinks they are got within reach, he descends, and taking a spear in his hand, strikes it into the fish; which, after wearying itself with its agitation, is seized and drawn into the boat. It is much esteemed by the Sicilians, who buy it up eagerly, and at its first coming into season give about sixpence English *per* pound. The season lasts from May till August. The ancients used to cut this fish into pieces, and salt it; whence it was called *Tonus Thurianus*, from Thurii, a town in the bay of Tarentum, where it was taken and cured.

The sword-fish is said to be very voracious, and that it is a great enemy to the tunny, who (according to Belon) are as much terrified with it as sheep are at the sight of a wolf. It is a great enemy to the whales, and frequently destroys them. See **BALÆNA**.

XYLO-ALOES, or **ALOE-WOOD**. See **ALOE**.

This drug is distinguished into three sorts; the calambac, the common lignum aloes, and calambour.

The calambac, or finest aloes-wood, called by authors *lignum aloes præstantissimum*, and by the Chinese *sukiang*, is the most refinous of all the woods we are acquainted with: it is of a light spongy texture, very porous, and its pores so filled up with a soft and fragrant resin, that the whole may be pressed and dented by the fingers like wax, or moulded about by chewing in the mouth, in the manner of mastic. This kind, laid on the fire, melts in great parts like resin, and burns away in a few moments, with a bright flame and perfumed smell. Its scent, while in the mass, is very fragrant and agreeable; and its taste acrid and bitterish, but very aromatic and agreeable: it is so variable in its colour, that some have divided it into three kinds; the one variegated with black and purple; the second, with the same black, but with yellowish instead of purple; and the third, yellow alone like the yolk of an egg: this last is the least scented of the three; the substance, however, in them all, is the same in every respect, except their colour. It is brought from Cochinchina.

The lignum aloes vulgare is the second in value. This is of a more dense and compact texture, and consequently less refinous than the other; there is some of it, however, that is spongy, and has the holes filled up with the resin refinous matter; and all of it, when good, has veins of the same resin in it. We meet with it in small fragments, which have been cut and split from larger: these are of a tolerably dense texture in the more solid pieces, and of a dusky brown colour, variegated with resinous black veins. It is in this state very heavy, and less fragrant than in those pieces which show a multitude of little holes, filled up with the same blackish matter that forms the veins in others. The woody part of these last pieces is somewhat darker than the other, and is not unfrequently purplish, or even blackish. The smell of the common aloes-wood is very agreeable, but not so strongly perfumed as the former. Its taste is somewhat bitter and acrid, but very aromatic. This wood is also brought from Cochinchina, and sometimes from Sumatra.

The calambour, or, as some write it, calambouc, is also called *agallochum sylestre*, and *lignum aloes mexicanum*. It is a light and friable wood, of a dusky and often mottled colour, between a dusky green black and a deep brown. Its smell is fragrant and agreeable, but much less sweet than that of either of the others; and its taste bitterish, but not so much acrid or aromatic as either of the two former. We meet with this very frequent, and in large logs; and these sometimes entire, sometimes only the heart of the tree, the cortical part being separated. This is brought from the island of Timor, and is the aloes-wood used by the cabinet-makers and inlaiders.

The Indians use the calambac by way of incense, burning small pieces of it in the temples of their gods; and sometimes their great people burn it in their houses in times of feasting. It is esteemed a cordial taken inwardly; and they sometimes give it in disorders of the stomach and bowels, and to destroy the worms. A very fragrant oil may be procured from it by distillation; which is recommended in paralytic cases, from five to fifteen drops. It is at present, however, but little used; and would scarce be met with any where in the shops, but that it is an ingredient in some of the old compositions.

XYNOECIA, in Grecian antiquity, an anniversary feast, observed by the Athenians in honour of Minerva, upon the sixteenth of Hecatombæon, in memory that, by the persuasion of Theseus, they left their country-seats, in which they lay dispersed here and there in Attica, and united together in one body.

XYSTARCHA, in antiquity, the master or director of the xylus. In the Greek gymnasium, the xylarcha was the second officer, and the gymnasiarcha the first; the former was his lieutenant, and presided over the two xylis, and all exercises of the athletes therein.

XYSTUS, among the Greeks, was a long portico, open or covered at the top, where the athletes practised wrestling and running; the gladiators, who practised therein, were called *xystici*.

Among the Romans, the xylus was only an alley, or double row of trees, meeting like an arbour, and forming a shade to walk under.

Xylo
Xylus.

Y.

Y
Yards.

Y or y, the 23d letter of our alphabet: its sound is formed by expressing the breath with a sudden expansion of the lips from that configuration by which we express the vowel *u*. It is one of the ambigential letters, being a consonant in the beginning of words, and placed before all vowels, as in *yard, yield, young*, &c. but before no consonant. At the end of words it is a vowel, and is substituted for the sound of *i*, as in *try, defery*, &c. In the middle of words it is not used so frequently as *i* is, unless in words derived from the Greek, as in *chyle, empyreal*, &c. though it is admitted into the middle of some pure English words, as in *dying, flying*, &c. The Romans had no capital of this letter, but used the small one in the middle and last syllables of words, as in *corymbus, onyx, martyr*. **Y** is also a numeral, signifying 150, or, according to Baronius, 159; and with a dash a-top, as **Y**, it signifies 150,000.

YACHT, a vessel of state, usually employed to convey princes, ambassadors, or other great personages from one kingdom to another.

As the principal design of a yacht is to accommodate the passengers, it is usually fitted with a variety of convenient apartments, with suitable furniture, according to the quality or number of the persons contained therein.

The royal yachts are commonly rigged as ketches, except the principal one reserved for the sovereign, which is equipped with three masts like a ship. They are in general elegantly furnished, and richly ornamented with sculpture; and always commanded by captains in his majesty's navy.

Besides these, there are many other yachts of a smaller kind, employed by the commissioners of the excise, navy, and customs; or used as pleasure-boats by private gentlemen.

YAMS. See **DIOSCOREA**.

YAMBOO. See **EUGENIA**.

YARDS of a **SHIP**, a long piece of timber suspended upon the masts of a ship, to extend the sails to the wind. See **MAST** and **SAIL**.

All yards are either square or lateen; the former of which are suspended across the masts at right angles; and the latter obliquely.

The square yards (fig. 1. Plate CCLX.) are nearly of a cylindrical surface. They taper from the middle, which is called the *flings*, towards the extremities which are termed the *yard arms*; and the distance between the flings and the yard-arms on each side, is, by the artificers, divided into quarters, which are distinguished into the first, second, third quarters, and yard-arms. The middle quarters are formed into eight squares, and each of the end parts is figured like the fruitum of a cone. All the yards of a ship are square except that of the mizen.

The proportions for the length of yards, according

to the different classes of ships in the British navy, are as follows:

| | | Guns. |
|--------------------|-----------|-------------------------------------|
| | { 560 : } | main-yard expref { 100 |
| | { 559 : } | fed by <i>d, d</i> , fig. 1 { 90 80 |
| | { 570 : } | Plate CCLX. { 70 |
| 1000 : gun-deck : | { 576 : } | Note, the figures { 60 |
| | { 575 : } | reprefents the { 50 |
| | { 561 : } | yard and falls of { 44 |
| | { 880 : } | a fhip of 74 guns. { 100 90 80 |
| 1000 : main-yard : | { 874 : } | fore yard. { all the reft. |

To apply this rule to practice, fuppofe the gun-deck 144 feet. The proportion for this length is as 1000 is to 575, fo is 144 to 83; which will be the length of the main-yard in feet, and fo of all the reft.

| | | Guns. |
|----------------------------|-----------|-------------------------------------|
| 1000 main-yard : | { 820 : } | { 100 90 80 60 44 |
| | { 847 : } | mizen-yd. { 24 |
| | { 840 : } | |
| 1000 : main-yard : | { 726 : } | main topfail-yard { 24 |
| | { 720 : } | do. { all the reft. |
| | { 719 : } | |
| 1000 : fore-yard : | { 726 : } | fore topfail yard { 24 |
| | { 715 : } | do. { all the reft. |
| 1000 : main topfail-yard : | { 690 : } | main top gall.-yard { all the reft. |
| | { 696 : } | fore top gall.-yard { 70 |
| 1000 fore topfail yard : | { 690 : } | do. { all the reft. |
| | { 688 : } | |
| 1000 : fore topfail yard : | { 750 : } | mizen topfail-yard { all the reft. |

Crofs-jack and fprit-fail yards equal to the fore topfail-yard.

Sprit-topfail-yard equal to the fore top-gallant-yard.

The diameters of yards are in the following proportions to their length.

The main and fore yards five fevenths of an inch to one yard. The topfail, crofs-jack, and fprit-fail yards, nine fourteenths of an inch to one yard. The top-gallant, mizen top-fail, and fprit-fail topfail yards, eight thirteenths of an inch to one yard.

The mizen-yard five ninths of an inch to one yard.

All fting-fail booms and yards half an inch to one yard in length.

The lifts of the main-yard are exhibited in the above figure, by *g*; the horfes and their ftirrups, by *h, i*; the reef-tackles and their pendants, by *k, l*; and the braces and brace-pendants, by *m, n*.

The lateen-yards evidently derive their names from having been peculiar to the ancient Romans. They are usually compofed of feveral pieces faftened together by woodings, which alfo ferve as fteps whereby the failors climb to the peak or upper extremity, in order to furl or call loofe the fail.

The mizen-yard of a fhip, and the main-yard of a bilander, are hung obliquely on the maff, almofl in the fame manner as the lateen-yard of a xebec, fettee, or polacre.

YARD,

Yard
||
wining.

YARD, a measure of length used in Britain and Spain, consisting of three feet, chiefly to measure cloth, stuffs, &c.

YARD-Arm is that half of the yard that is on either side of the mast, when it lies athwart the ship.

YARDS also denotes places belonging to the navy, where the ships of war, &c. are laid up in harbour.—There are belonging to his majesty's navy six great yards, viz. Chatham, Deptford, Woolwich, Portsmouth, Sheerness, and Plymouth; these yards are fitted with several docks, wharfs, lanches, and, graving places, for the building, repairing, and cleaning of his majesty's ships; and therein are lodged great quantities of timber, masts, planks, anchors, and other materials: there are also convenient store-houses in each yard, in which are laid up vast quantities of cables, rigging, sails, blocks, and all other sorts of stores needful for the royal navy.

YARE, among sailors, implies ready or quick: as, be yare at the helm; that is, be quick, ready, and expeditious at the helm. It is sometimes also used for bright by seamen: as, to keep his anns yare; that is, to keep them clean and bright.

YARE, a river of Norfolk, which runs from west to east through that county, passing by Norwich, and falling into the German sea at Yarmouth.

YARMOUTH, a sea-port town of Norfolk, with a market on Wednesdays and Saturdays, and a fair on Friday and Saturday in Easter-week for petty chapmen. It is situated on the river Yare, where it falls into the sea, and is a place of great strength, both by art and nature, being almost surrounded with water; and there is a draw-bridge over the river. It is esteemed the key of this coast, and is a clean handsome place, whose houses are well built, it being a considerable town for trade. It has one large church, and a neat chapel, and the steeple of St Nicholas's is so high, that it serves for a sea-mark. It is governed by a mayor. The harbour is a very fine one, though it is very dangerous for strangers in windy weather; and it has for its security a pretty strong fort. It is 27 miles east of Norwich, and 123 north-east of London. E. Long. 2. o. N. Lat. 52. 45.

YARMOUTH, a town of the Isle of Wight, in Hampshire, with a market on Fridays, and one fair on July 25th for toys. It is seated on the western part of the island, on the sea-shore, and is encompassed with water; for not many years ago a channel was cut through the peninsula, over which there is a draw-bridge, and it is defended by a strong castle on the quay. It is a handsome place, whose houses are chiefly built with stone, and covered with slate; and it sends two members to parliament. The market is now dissolved.

YARN, wool or flax spun into thread, of which they weave cloth. See **CLOTH**.

YAWNING, an involuntary opening of the mouth, occasioned by a vapour or ventosity endeavouring to escape, and generally witnessing an irksome weariness, or an inclination to sleep. Yawning, according to Boerhaave, is performed by expanding at one and the same time all the muscles capable of spontaneous motion; by greatly extending the lungs; by drawing in gradually and slowly a large quantity of air; and gradually and slowly breathing it out, after it has been retained for some time and rarified; and then restoring the muscles to their natural state. Hence the effect

of yawning is to move, accelerate, and equally distribute all the humours through all the vessels of the body, and consequently to qualify the muscles and organs of sensation for their various functions.

Sanctorius observes, that a great deal is insensibly discharged, when nature endeavours to get rid of the retained perspirable matter, by yawning and stretching of the limbs. To these a person is most inclined just after sleep, because, a greater quantity going off by the pores of the skin than at other times, whensoever a person wakes, the increased contraction that then happens closes a great deal of the perspirable matter in the cutaneous passages, which will continually give such irritations as excite yawning and stretching; and such motions, by shaking the membranes of the whole body, and shifting the contacts of their fibres, and the inclosed matter, by degrees throw it off. Hence we see the reason why healthful strong people are most inclined to such motions, because they perspire most in time of sleep, and therefore have more of the perspirable matter to lodge in the pores, and greater irritations thereunto. The advantages of some little exercise just after waking in a morning are considerable, as it throws off all the perspirable matter that is ready for its exit out of the body. When yawning is troublesome, Hippocrates says, that long deep respiration, or drawing in the air at long intervals, cures it.

YEAR, in astronomy and chronology. See **ASTRONOMY**, n° 289—296.

YELL, one of the islands of Shetland, lying north-east from the main land, and divided from it by an arm of the sea, called *Yell-Sound*. By some it is thought to have been the *Thule* of the ancients. In the old descriptions it is said to be 20 miles long, and eight broad. It is very mountainous and full of moss; but there are pretty considerable pastures in which they feed a great many sheep; and it also affords plenty of peat. It has eight large harbours, which would not be thought despicable in other countries. Anciently it seems to have been pretty populous, since there are in it three churches, 20 chapels, and many brughs or Pictish forts.

YELLOW, one of the original colours of light.

YELLOW-Colour for House-painting. See **CHEMISTRY**, n° 148.

Naples YELLOW, a beautiful colour much used by painters, formerly thought to be prepared from arsenic, but now discovered to have lead for its basis.

YELLOW-Hammer, in ornithology. See **FRINGILLA**.

YELLOW-Fever. See **MEDICINE**, n° 416, 417, 434.

YEOMAN, the first or highest degree among the plebians of England, next in order to the gentry.

The Yeomen are properly freeholders, who having land of their own, live on good husbandry.

YEOMAN is also a title of office in the king's household, of a middle place or rank between an usher and a groom.

YEOMAN of the Guard were anciently 250 men of the best rank under gentry, and of larger stature than ordinary, each being required to be six feet high.

At present there are but 100 yeomen in constant duty, and 70 more not in duty; and as any of the 100 dies, his place is supplied out of the 70.

They go dressed after the manner of king Henry VIII's

Year
||
Yeoman.

Yeovil
York.

VIII's time. They formerly had diet as well as wages when in waiting; but this was taken off in the reign of queen Anne.

YEOVIL, a market-town of Somersetshire, situated 18 miles south of Wells.

YEST, a head or scum rising upon beer or ale, while working or fermenting in the vat. See BREWING.

It is used for a leaven or ferment in the baking of bread, as serving to swell or puff it up very considerably in a little time, and to make it much lighter, softer, and more delicate. See BAKING, BREAD, and BARM.

The making of yeast was formerly a great desideratum in the arts; but of late Mr Henry has published a process, by which he says it can be originally produced without any previous fermentation. The process consists in impregnating a mixture of molasses and flour with fixed air; and this mixture is afterwards found to act as a ferment to other substances.

YEW, in botany. See TAXUS.

YLA, one of the western islands of Scotland, situated in the Irish sea, west of Cantire. See ILLA.

YNCA, an appellation anciently given to the kings of Peru, and the princes of their blood; the word literally signifying lord, king, emperor, and royal blood.

YOAK, or YOKE, in agriculture, a frame of wood, fitted over the necks of oxen, whereby they are coupled together, and harnessed to the plough.

YOAK of land in our ancient customs, was the space which a yoke of oxen, that is, two oxen, may plow in one day.

YOLK, the yellow part in the middle of an egg. See EGG. The yolk is endued with an anodyne, maturing, digesting, and relaxing virtue. Hence it is very often an ingredient in clysters, and mixed with a little fat, is commonly applied, in a walnut shell, to the navels of infants, in order to loosen the belly.

YONNE, a river in France, which rising in Burgundy, and running north through Nivernois and Champaign, falls into the Seyne at Montereau fur Yonne.

YORK, in Latin *Eboracum*, the capital of Yorkshire in England. This city is so ancient that the origin of it is uncertain. In the time of the Romans a legion was stationed here, it being then the capital of the Brigantes; and here died the emperor Severus, and Flavius Valerius Constantius Chlorus, father of Constantine the Great. There was then also a temple of Bellona here, and no less than three military ways went from hence. In the time of the Saxons it was erected into an archbishopric by pope Honorius, to which are now subject the bishoprics of Chester, Durham, Carlisle, and the Isle of Man; though anciently 12 bishoprics in England, and all Scotland, were. A horn is still kept in theminster, by which Ulphius, one of the Saxon princes, bestowed all his lands and revenues upon the church.

This city suffered very much during the ravages of the Danes; but, after the conquest, it began to flourish again. The cathedral, which cost a long time and a great deal of money in building, is a most stately Gothic pile. Its chapter-house is particularly admired for its painted glass, its fine marble stalls, its pil-

lars of alabaster, and curious contrivance. In it is the following line in gold letters:

Ut Rosa, flos florum, sic est Domus ista Donorum.

The choir is remarkable for its fine carvings, particularly the statues of all the English monarchs; and the windows are exquisitely painted with the history of the Bible. The lanthorn steeple is 70 feet square, and 188 high, and the windows are 45. At the south end is a circular light, called the *marigold window* from the colour of its glass; and at the north end is a very large one, whose painting represents embroidery.—Here, in the reign of Richard I. was a barbarous massacre of the Jews; and Henry III. had, in this place, an interview with Alexander king of Scots. Several parliaments were held here in the reigns of Edward I. and II. A tribunal, not unlike the parliaments of France, was established at York by Henry VIII. to decide all causes in these northern parts, according to the rules of equity.

This city, as hath been already observed, is a county of itself; and its jurisdiction extends over 36 villages and hamlets in the neighbourhood. It is generally reckoned the second city in England; but though it stands upon more ground, it is inferior in trade, wealth, and number of people, to Bristol. It is situated in a fine plain, in the middle of the shire, on both sides the Ouse, walled, and divided into four wards, containing 28 parishes. It enjoys large privileges and immunities, conferred upon it by a succession of kings from Henry II. and its chief magistrate has the title of *lord-mayor*, which is an honour peculiar to it and London. Richard II. made it a county of itself. The conservancy of most of the rivers of the county, within certain limits, belongs to the lord-mayor and aldermen. The middle arch of the bridge here over the Ouse, is thought to equal the Rialto at Venice, in architecture, height, and breadth, the diameter being 81 feet, and the height 51. Though this city is 60 miles distant from the sea, yet ships of 70 tons burden come up the river to it. The town-house, or Guildhall, stands upon the bridge, and is superior in all respects to that of London. In the Popish times there were nine albeys here, and a vast number of churches; but of the latter there are only 17 now. The steeple of that of Allhallows, is reckoned the finest in England. The archbishop has a fine palace; and the assembly-room, designed by the earl of Burlington, is very noble. Here are plays, assemblies, concerts, and the like entertainments, at some house or other, almost every night in the week. In the old castle, built originally by William the Conqueror, and repaired in 1701, the assizes are kept. It serves also for the county goal, which is the neatest and pleasantest in England, with an area larger than that of the King's-bench, and has a handsome chapel in it, with a good allowance for a preacher. This city has long given the title of *duke* to some branch of the royal family, and lately to his royal highness Edward, next brother to his present majesty George III. who was carried off by a violent fever at Monaco in Italy, in the flower of his age, to the great grief of the nation and the royal family.

The plenty and cheapness of provisions induces many persons of small fortune, or that would live frugally,

to

York.

to take up their abode here; and the venerable remains of Roman antiquities, and those of a latter date, as abbeys, churches, and castles, procure this city a visit from every curious traveller. Many Roman altars, urns, coins, inscriptions, &c. have been found; and Saxon coins are still extant that have been struck here. The members for this city have precedence of all others, except those of London, in the house of commons. An infirmary, after the manner of those of Bath, Bristol, &c. hath been erected in it; and a cotton manufacture (established, and brought to great perfection. Besides four weekly markets, it has a great many fairs; one, in particular, every other Thursday, for cattle and sheep.

YORKSHIRE, the largest county of England, bounded on the south by Derbyshire, Nottinghamshire, and Lincolnshire; on the north by Durham and Westmoreland; on the east by the German ocean; and on the west by Lancashire, and a part of Cheshire.—It is upwards of 80 miles in length from east to west, near as much in breadth, and about 360 in circumference, containing, in the whole, 26 hundreds or wapentakes, 49 market-towns, 563 parishes, 242 vicarages, with many chapels of ease, and 2330 villages. Its area is computed by some at 4684 square miles, by others at 3,770,000 acres, and its inhabitants at upwards of 530,000. It is divided into three parts, or ridings, viz. the West, East, and North; so denominated from their situation, in respect of the city of York. Each of these is as large, if not larger, than any ordinary county. There are other divisions, as Richmondshire, Allertonshire, Howdenshire, Hallamshire, Craven, Cleveland, Marsfield, Holderness, &c.

As the soil and face of the country vary greatly, so does the air. In the hilly parts the air is good, but the soil very indifferent; of the lower, some are marshy, others drier, and the soil of both rich; but the air of the former is more foggy and unhealthy than that of the latter.

The manufactures of this county are cutlery and hard-ware; particularly knives, bits, and spurs; but the principal are stockings and woollen cloth, with which it supplies, in a great measure, Germany and the North. As to the produce, it abounds in corn, cattle, horses, lead, and iron, coal, wood, lime, liquorice, alum, jet, &c. It lies wholly in the northern circuit, and much the greater part of it in the diocese of York; that only which is called *Richmondshire*, belonging to the diocese of Chester. The members it sends to parliament are 30; of which two are for the shire, and 28 for the towns.

YORK (*New*), one of the United States of America. It is bounded on the east by New-England; on the north by Canada; on the south by New-Jersey; and on the west by Delaware river. It produces corn, abounds in cattle, and has a good breed of horses; but the inhabitants are chiefly employed in fisheries. They supply the Caribbee islands with flour, salt-beef, pork, salt-fish, horses, and timber. They export a great deal of dried and salted fish to Europe; as also logwood, train oil, and whalebone. There are some forts on the north to defend them against the native Americans.

YORK (*New*), the capital of the province of New-York, in North-America, seated in an island at the

mouth of Hudson's river. It stands on an eminence, and is surrounded with a wall, and has other fortifications. It has a spacious harbour, with commodious quays, as well as warehouses. It is frequented by a great number of ships employed in trade, and in the fisheries. W. Long. 74. 40. N. Lat. 39. 40.

YOUNG (Dr Edward), was the son of a clergyman of the same name, and was born about the year 1679. When sufficiently qualified, he was matriculated into All-Souls college, Oxford; and desirous to follow the civil law, he took a degree in that profession. In this situation he wrote his poems called *The Last Day*, published in 1704; which coming from a layman gave universal satisfaction: this was soon after followed by another, intitled *The Force of Religion*, or *Vanquished Love*. These productions gained him a respectable acquaintance; he was intimate with Addison, and thus became one of the writers of the Spectator: but the turn of his mind leading him to the church, he took orders, was made one of the king's chaplains, and obtained the living of Welwyn in Hertfordshire, worth about 500*l. per annum*, but he never rose to higher preferment. For some years before the death of the late prince of Wales, Dr Young attended his court pretty constantly; but upon his decease, all his hopes of church preferment vanished; however, upon the death of Dr Hales, he was taken into the service of the princess dowager of Wales, and succeeded him as her privy chaplain. When pretty far advanced in life, he married the lady Elizabeth Lee, daughter of the late earl of Litchfield. This lady was a widow, and had an amiable son and daughter, who both died young. What he felt for their loss, as well as for that of his wife, is finely expressed in his *Night Thoughts*, in which the young lady is characterized under the name of Narcissa; her brother by that of Philander; and his wife, though nameless, is frequently mentioned: and he thus, in an apostrophe to death, deprecates the loss of all the three:

Insatiate archer, could not once suffice!

Thy shafts flew thrice, and thrice my peace was slain,
And thrice ere thrice yon moon renew'd her horn.

He wrote three tragedies, *The Revenge*, *Basilin*, and *The Brothers*. His satires, called *Love of Fame the universal Passion*, are by many esteemed his principal performance; though Swift said the poet should have been either more angry or more merry: they have been characterized as a string of epigrams written on one subject, that tire the reader before he gets through them. His *Complaint*, or *Night Thoughts*, exhibit him as a moral and melancholy poet, and are esteemed his master-piece. They form a species of poetry peculiarly his own, and in which he has been unrivalled by all those who attempted to write in this manner. They were written under the recent pressure of his sorrow for the loss of his wife, daughter, and son-in-law; they are addressed to Lorenzo, a man of pleasure and the world, and who, as it is insinuated by some, is his own son, but then labouring under his father's displeasure. As a prose-writer he arraigned the prevailing manners of his time, in a work called *The Centaur not Fabulous*; and when he was above 80 years of age, published *Conjectures on Original Composition*. He published some other pieces; and the whole of his works are collected in 4 and 5 vols 12mo.

Dr

Young
||
Ypres.

Dr Young's turn of mind was naturally solemn; and he usually, when at home in the country, spent many hours of the day walking in his own church-yard among the tombs. His conversation, his writings, had all a reference to the life after this; and this turn of disposition mixed itself even with his improvements in gardening. He had, for instance, an alcove with a bench, so painted near his house, that at a distance it looked as a real one, which the spectator was then approaching. Upon coming up near it, however, the deception was perceived, and this motto appeared, *Invisibilia non decipiunt*, "The things unseen do not deceive us." Yet, notwithstanding this gloominess of temper, he was fond of innocent sports and amusement; he instituted an assembly and a bowling-green in the parish of which he was rector, and often promoted the gaiety of the company in person. His wit was generally poignant, and ever levelled at those who testified any contempt for decency and religion. His epigram, spoken extempore upon Voltaire, is well known; who happening in his company to ridicule Milton, and the allegorical personages of Death and Sin, Young thus addressed him:

Thou art so witty, profligate, and thin,
You seem a Milton with his Death and Sin.

One Sunday preaching in office at St James's, he found, that though he strove to make his audience attentive, he could not prevail. Upon which his pity for their folly got the better of all decorums, and he sat back in the pulpit, and burst into a flood of tears. Towards the latter part of life, he knew his own infirmities, and suffered himself to be in pupillage to his house-keeper; for he considered that, at a certain time of life, the second childhood of age demanded its wonted protection. His son, whose boyish follies were long obnoxious to paternal severity, was at last forgiven in his will; and our poet died regretted by all, having performed all that man could do to fill his post with dignity. His death happened in 1765.

YOUTH, that state of man, in which he approaches towards his greatest perfection of body.— In this state, according to Dr Cullen, rigidity and strength are now greater, but still, with respect to the middle point, laxity prevails; a less proportion of fluids, with respect to the vessels, but still prevailing humidity; increased cellular substance, on which the growth of the body chiefly depends till the acme, and long after; heart less in proportion to the system than formerly, and more in a balance with it; the arteries are diminished, in some measure, with respect to the veins, but still exceed them; the whole viscera are larger, and particularly the lungs; and, as the vessels are more rigid, consequently a greater determination of fluids to that organ, which explains the diseases incident to the stage of life, hæmoptoeis, peripneumony, &c. The same sensibility and irritability continue, perhaps, as before, but the former is more accurate, from the tension of the vessels, and consequently the fibres. The latter is rather encreased, and hence irascibility more frequently appears at this period. There is also great mobility, but with much less levity.

YPRES, a handsome, large, and populous town of the Aultrian Netherlands, with a bishop's see. It

has a considerable manufactory in cloth and serges, and every year in Lent there is a considerable fair. It is one of the barrier towns, but was besieged and taken by the French in 1744. It is seated on a fertile plain on the river Ypre, in E. Long. 2. 58. N. Lat. 50. 51.

YUCCA, ADAM'S NEEDLE; a genus of the monogynia order belonging to the hexandra class of plants.

Species. 1. The gloriosa, or common Adam's needle; rises with an erect, ligneous, thick stem two or three feet high, having very long, narrow, stiff, entire leaves ending in a long, sharp, black-spine, garnishing the stem almost to the bottom and in a large tuft at top; and from the centre of the top leaves rises a long branching peduncle, sustaining a panicle of bell-shaped white and purple flowers.

2. The filamentosa, or Virginia yucca; rises with an upright, thick, ligneous stem two or three feet high, adorned at top with a tuft of very long, spear-shaped, stiff, blunt-pointed, sawed filamentous leaves, emitting long threads from the sides, hanging downward; and from the top of the stem amidst the leaves an erect peduncle or flower-stalk, several feet high, garnished with many large, white, and purple-striped leaves. Both these species flower in August and September, and make an ornamental appearance, but are not succeeded by seeds in this country. They are natives of North America, the former that of Canada, and the latter of Virginia, and are both tolerably hardy.

3. The aloifolia, or aloe-leaved yucca; rises with an erect, thick, fleshy stem, eight or ten feet high, crowned with a large tuft of long narrow, stiff, cre-nated, aloe-like leaves, ending in sharp spines; and from the centre of the crown of leaves come out the flower-stalk, branching pyramidally two or three feet high, having all the branches terminating in a spike of flowers, purple without and white within, appearing in August and September.

4. Draconis, or tree-leaved yucca; rises with an upright, thick, brown stem, three feet high, crowned with long, narrow, serrated leaves ending in spines and nod downward; and in the centre of the leaves arise the flower-stalk very branchy, with all the branches terminating in spikes of flesh-coloured flowers in August and September.

All these four species of yucca, being of singularly curious growth, are worthy of culture in every good collection, keeping some of all the sorts in pots, to move to shelter of a green-house in winter, as they will afford a conspicuous and entertaining variety in this collection: some plants of the two first sorts may also, after attaining a little strength and gradually hardened, be planted out in the full ground in some dry warm situation, sheltered by adjacent shrubs and trees. As all the sorts are of a succulent nature, they should always be planted in a light dry soil; if somewhat sandy the better. The propagation of all the sorts is by off-sets and suckers, from the root and head of the plants; also by seed. The two last kinds being tender, cannot bear the open air.

Uss. A kind of bread is made from the roots of this plant by the Indians, which much resembles that from the Cassia. See JATROPHA.

Yucca

Z.

Z,
ARTO.

Z, or **z**, the twenty-fourth and last letter, and the nineteenth consonant of our alphabet; the sound of which is formed by a motion of the tongue from the palate downwards and upwards to it again, with a shutting and opening of the teeth at the same time. This letter has been reputed a double consonant, having the sound *dz*; but some think with very little reason; and, as if we thought otherwise, we often double it, as in *puzzle*, *muzzle*, &c. Among the ancients, **Z** was a numeral letter, signifying two thousand, and with a dash added a-top, **Z** signified two thousand times two thousand, or four millions.

In abbreviations this letter formerly stood as a mark for several sorts of weights; sometimes it signified an ounce and a half, and very frequently it stood for half an ounce; sometimes for the eighth part of an ounce, or a dram Troy weight; and it has in earlier times been used to express the third part of an ounce, or eight scruples. **ZZ** were used by some of the ancient physicians to express myrrh, and at present they are often used to signify zinziber, or ginger.

ZAARA, **ZAPARA**, or **SAHARA**, a barren and desert country of Africa, stretches itself from the Atlantic Ocean on the west, to the desert of Barca and Nubia on the east; that is, from the eighth degree of west to the twenty-sixth of east longitude; and from Biledulgerid on the north to Negroland on the south; or from the fifteenth degree of latitude quite to the tropic of Cancer, and even beyond; so that it will be about 400 or 500 miles in breadth, from north to south; and above 1500 in length, from east to west. The river Niger is its boundary to the south. It was known to the ancients by the name of Libya Interior, or Libya Deserta; and is supposed to have been then inhabited by the Getuli. At present it is mostly inhabited by Arabs, who, for the generality, are an ignorant, brutish, and savage people, who lead a wandering life, and live chiefly on the milk of their flocks, with a little barley-meal, and some dates. The poorer sort go naked, except the females, who commonly wrap a clout about their middle, and wear a kind of bonnet on their head; but the wealthier sort have a kind of loose gown, made of blue callicoe, with large sleeves, that is brought them from Negroland. Both sexes are very swarthy; the men tall and thin, but the women fat and lusty. When they move from one place to another for fresh pasture, water, or prey, most of them ride on camels, which have generally a sort of saddle between the bunch and the neck, with a string or strap run through their nostrils, which serves for a bridle; and instead of spurs they use a sharp bodkin. Their tents or huts are covered with a coarse stuff, made of camels hair, and a kind of wool or moss that grows on the palm trees. These Arabs live here under the government of their sheiks

or cheyks, as in Arabia, Egypt, and other places. Besides these Arabs, there is a people here who live in settled habitations, and are more civil and hospitable, carrying on a kind of commerce with strangers. The religion of both is a kind of Mohammedism.

ZABULON (anc. geog.), one of the twelve tribes, bounded on the north by the tribes of Asher and Naphthali, on the east by the sea of Galilee, on the south by the tribe of Issachar, or the brook Cison, which ran between both, on the west by the Mediterranean; so that it touched two seas, or was bimarous.

ZABULON (anc. geog.), a very strong town in the tribe of that name, on the Mediterranean, surnamed *of men*, near Ptolemais: its vicinity to which makes it probable that it was also Chabulon, unless either name is a faulty reading in Josephus; distant about 60 stadia from Ptolemais.

ZACYNTHUS (anc. geog.), an island to the south of Cephalenia 60 stadia, but nearer to Peloponnesus, in the Ionian sea, formerly subject to Ulysses, in compass above 160 stadia, woody and fruitful, with a considerable cognominal town, and a port. The island lies over against Elis, having a colony of Achæans from Peloponnesus, over-against the Corinthian Gulf. Both island and town are now called *Zante*, to the west of the Morea, and south of Cephalonia. E. Long. 21. 30. N. Lat. 37. 50.

ZAFFRE, or **SAFFRE**, is the residuum of cobalt, after the sulphur, arsenic, and other volatile matters of this mineral have been expelled by calcination. It is therefore a kind of calx of cobalt, of a grey or reddish colour. The use of cobalt is to produce a very fine blue colour, when it is melted with fusible and vitrifiable matters. This blue colour produced by the vitrification of zaffre proceeds from the earth or calx of a semi-metallic substance contained in cobalt, called by chemists *regulus of cobalt*. This is proved by melting zaffre with a reducing flux, like any other roasted ore; by which means the above-mentioned semi-metallic regulus of cobalt will be obtained. The scoria in this fusion has also a blue colour, which proceeds from a portion of the calx of this regulus that is not reduced, but is vitrified along with the scoria. The calx therefore or metallic earth of the regulus of cobalt is the sole cause of the blue colour produced by zaffre. But as the quantity of regulus contained in cobalt is variable, therefore some zaffres furnish more blue than others. The heterogeneous fixed matters contained in cobalts, contribute, according to their quantity, not only to the greater or less intensity of the blue colour, but also to its lustre and beauty. For which reason, those who manufacture zaffre from cobalt, make frequent essays of the roasted ore, by mixing it with vitreous matters, to discover the intensity and beauty of the blue colour. Good cobalts calcined would form

Zabulon
||
Zafre.

Zaleucus
||
Zama.

too deep a blue, and almost a black glass, if they were not previously mixed with a certain quantity of vitreous frit. In the manufacture of zaffre, therefore, the calx of cobalt, the strength of which has been previously determined by essays, is mixed with such a quantity of sand, or of powdered flints and quartz, that with the addition of some saline flux, a deep blue glass may be formed. The zaffre that is commonly sold, and which comes from Saxony, is a mixture of calx of cobalt with some vitrifiable earth, as we have said. It is of a grey colour, as all calxes of cobalt are before vitrification. Some zaffres are dearer than others, according to the intensity of the colour which they are capable of producing. Zaffre is employed in the manufacture of pottery and of porcelain, for painting the surface of the pieces of ware upon which it is applied together with some saline flux, previously to the baking or glazing, that the same fire may also vitrify this colouring material.

The blue of zaffre is the most solid and fixed of all the colours that can be employed in vitrification. It suffers no change from the most violent fire. It is successfully employed to give shades of blue to enamels, and to the crystal-glasses made in imitation of some opaque and transparent precious stones, as the lapis lazuli, the turquois, the saphire, and others of this kind.

ZAŁEUCUS, a famous legislator of the Locrians, and the disciple of Pythagoras, flourished 500 years B.C. He made a law, by which he punished adulterers with the loss of both their eyes; and his son offending, was not absolved from this punishment: yet, to show the father as well as the just law-giver, he put out his own right, and his son's left eye. This example of justice and severity made so strong an impression on the minds of his subjects, that no instance was found of the commission of that vice during the reign of that legislator. It is added, that Zaleucus forbid any wine being given to the sick on pain of death, unless it was prescribed by the physicians; and that he was so jealous of his laws, that he ordered that whoever was desirous of changing them, should be obliged, when he made the proposal, to have a cord about his neck, in order that he might be immediately strangled, if those alterations were effected no better than the laws already established. Diodorus Siculus attributes the same thing to Charondas, legislator of the Sybarites.

ZALUSKI (Andrew Chrysofom), bishop of Plocko, and afterwards of Varnia, and grand chancellor of Poland, was the son of Alexander Zaluski, waiwode of Rawa. He had a great share in all the important affairs of the state, and died in 1711, aged 61. His principal work is a curious collection of Latin Letters, printed in 1709 and 1711, in 3 vols. folio. These letters contain the history of Poland, and interesting memoirs of Europe, during his own time.

ZAMA (anc. geog.), a town of Chamane, a district of Cappadocia, of unknown situation.—Another Zama, of Mesopotamia, on the Sacoras, to the south of Nisibis.—A third, of Numidia, distant five days journey to the west of Carthage: it was the other royal residence of the kings of Numidia, hence called *Zama Regia*. It stood in a plain; was stronger by art than nature; richly supplied with every necessary; and abounding in men, and every weapon both of defence and annoyance.

The last of these is remarkable for the decisive battle fought between the two greatest commanders in the world, Hannibal the Carthaginian and Scipio Africanus. Of this engagement, the most important perhaps that ever was fought, Mr Hooke gives us the following account.

“Scipio drew up his army after the Roman manner, except that he placed the cohorts of the Principes directly behind those of the Hastati, so as to leave sufficient space for the enemy's elephants to pass thro' from front to rear. C. Lælius was posted on the left wing with the Italian horse, and Masinissa with his Numidians on the right. The intervals of the first line Scipio filled up with his Velites, or light-armed troops, ordering them, upon a signal given, to begin the battle; and in case they were repulsed, or broke by the elephants, to run back through the lanes before mentioned, and continue on their flight till they were got behind the Triarii. Those that were wounded, or in danger of being overtaken, were to turn off to the right and left through the spaces between the lines, and that way escape to the rear.

“The army thus drawn up, Scipio went from rank to rank, urging his soldiers to consider the consequences of a defeat, and the rewards of victory: on the one hand, certain death or slavery; (for they had no town in Africa strong enough to protect them), on the other, not only a lasting superiority over Carthage, but the empire of the rest of the world.

“Hannibal ranged all his elephants, to the number of above 80, in one front. Behind these he placed his mercenaries, consisting of 12,000 men, Ligurians, Gauls, Baleares, and Mauritanians.

“The new levies of Carthaginians and other Africans, together with 4000 Macedonians, under a general named Sopater, composed the second line. And in the rear of all, at the distance of about a furlong, he posted his Italian troops, in whom he chiefly confided. The Carthaginian horse formed his right wing, the Numidians his left.

“He ordered their several leaders to exhort their troops, not to be discouraged by their own weakness, but to place the hope of victory in him and his Italian army; and particularly directed the captains of the Carthaginians to represent to them what would be the fate of their wives and children if the event of this battle should not prove successful. The general himself, walking through the ranks of his Italian troops, called upon them to be mindful of the 17 campaigns in which they had been fellow-soldiers with him; and of that constant series of victories, by which they had extinguished in the Romans all hope of ever being conquerors. He urged them to remember, above all, the battles of Trebia, Thrasymenus, and Cannæ; with any of which the approaching battle was in no wise to be compared, either with respect to the bravery, or the number of the enemy. “The Romans were yet unfoiled, and in the height of their strength when you first met them in the field; nevertheless you vanquished them. The soldiers now before us are either the children of the vanquished, or the remains of those whom you have often put to flight in Italy. Maintain therefore your general's glory and your own, and establish to yourselves the name of invincible, by which you are become famous throughout the world.”

“When

"When the Numidians of the two armies had skirmished a while, Hannibal ordered the managers of the elephants to drive them upon the enemy. Some of the beasts, frightened at the noise of the trumpets, and other instruments of war, which sounded on all sides, immediately ran back amongst the Numidians of the Carthaginian left wing, and put them into confusion; which Masinissa taking advantage of, entirely routed them. Great destruction was made of the Velites by the rest of the elephants, till these also being terrified, some of them ran through the void spaces of the Roman army which Scipio had left for that purpose; others falling in among the cavalry of the enemy's right wing, gave Lælius the same opportunity against the Carthaginian horse as had been given to Masinissa against the Numidian, and of which the Roman did not fail to make the same use. After this the infantry of the foremost lines joined battle. Hannibal's mercenaries had the advantage in the beginning of the conflict; but the Roman Hastati, followed and encouraged by the Princes, who exhorted them to fight manfully, and showed themselves ready to assist them, bravely sustained the attack, and at length gained ground upon the enemy. The mercenaries not being seasonably supported by their second line, and therefore thinking themselves betrayed, they in their retreat fell furiously upon the Africans; so that these, the Hastati coming up, were obliged to fight for some time both against their own mercenaries and the enemy. When the two Carthaginian lines had ceased their mutual rage, they joined their strength; and though now but a mere throng of men, broke the Hastati: but then the Princes advancing to the assistance of the latter, restored the battle; and most of the Africans and mercenaries were here cut off. Hannibal did not advance to their relief, the Roman Triarii not having yet engaged, and the Princes being still in good order: and left the routed Africans and mercenaries should break the ranks of his Italian soldiers, he commanded these to present their spears at those who fled to them for protection, which obliged the runaways to move off to the right and left.

"The ground over which the Romans must march before they could attack Hannibal, being strewed with heaps of dead bodies and weapons, and being slippery with blood, Scipio feared that the order of his battalions would be broke, should he pass it hastily. To avoid this mischief, he commanded the Hastati to give over the pursuit, and halt where they were, opposite to the enemy's centre: after which, having sent all his wounded to the rear, he advanced leisurely with the Princes and Triarii, and placed them on the wings of the Hastati. Then followed a sharp engagement, in which victory was long and eagerly disputed. It would seem that the Romans, though superior in number, were once upon the point of losing the day; for Polybius tells us, that Masinissa and Lælius came very seasonably, and as if sent from heaven, to their assistance. These generals being returned from the pursuit of the cavalry, fell suddenly upon the rear of Hannibal's men, most of whom were cut off in their ranks; and of those that fled, very few escaped the horse, the country all around being a plain.

"There died of the Carthaginians in the fight above 20,000, and almost the like number were taken

prisoners. The loss on the side of the Romans amounted to about 2000 men. Hannibal escaped with a few horse to Adrumetum, having performed every thing in the engagement which could be expected from a great general. His army (says Polybius) could not have been more skillfully drawn up. For as the order of the Roman battalions makes it extremely difficult to break them, the Carthaginian wisely placed his elephants in the front, that they might put the enemy in confusion before the armies should engage. In his first line he placed the mercenaries; men bold and active, but not well disciplined, that by their impetuosity he might give a check to the ardour of the Romans. The Africans and Carthaginians, whose courage he doubted, he posted in the middle between the mercenaries and his Italian soldiers, that they might be forced to fight, or at least that the Romans, by slaughtering them, might fatigue themselves and blunt their weapons. Last of all, he drew up the troops he had disciplined himself, and in whom he chiefly confided, at a good distance from the second line, that they might not be broken by the route of the Africans and mercenaries, and kept them in reserve for a vigorous attack upon a tired and weakened enemy."

ZANGUEBAR, a country in Africa, lying on the eastern coast, between 3 degrees of north latitude, and 18 south. It includes several petty kingdoms, in which the Portuguese have various settlements. The inhabitants, except those converted by the Portuguese, are all Mahometans or Idolaters; and the latter much the more numerous. The names of the principal territories are *Mombaza, Lamou, Melinda, Quiloa, and Mosambique*. The Portuguese have built several forts in Mombaza and Mosambique, and have settled several colonies there. They trade with the Negroes for slaves, ivory, gold, ostrich-feathers, wax, and drugs. The productions are much the same as in other parts of Africa between the tropics.

ZANTE, an island of the Mediterranean, near the coast of the Morea, 17 miles south-east of the island of Cephalonia, belonging to the Venetians. It is about 24 miles in length, and 12 in breadth, and very pleasant and fertile; but its principal riches consist in currants, with which it greatly abounds. They are cultivated in a very large plain, under the shelter of mountains on the shore of this island; for which reason the sun has greater power to bring them to perfect maturity. Here are also the finest peaches in the world, each of which weigh 8 or 10 ounces. Here are also cucumbers and excellent figs, and a great deal of very good oil. The town called Zante may contain near 20,000 inhabitants. The houses are low, on account of the frequent earthquakes, for scarce a year passes without one; however, they do no great damage. The natives speak both Greek and Italian. There are very few Roman Catholics among them; but they have a bishop as well as the Greeks. This place has no fortifications, but there is a fortress upon an eminence planted with cannon. In one part of this island is a place which shakes when trod upon like a quagmire; and a spring which throws out a great deal of bitumen, especially at the time of an earthquake. It serves instead of pitch to pay the bottoms of the ships, and about 100 barrels in a year are used for this purpose. There are about 50 villages in the island; but no other

Zama
||
Zante.

Zapata,
Zea.

large town beside Zante. It is seated on the eastern side of the island, and has a good harbour. The English and Dutch have each a factory and consul here. E. Long. 21. 15. N. Lat. 37. 57.

ZAPATA, a kind of feast or ceremony held in Italy, in the courts of certain princes, on St Nicholas's day; wherein people hide presents in the shoes or slippers of those they would do honour to, in such a manner as may surprise them on the morrow when they come to dress; being done in imitation of the practice of St Nicholas, who used in the night-time to throw purses of money in at the windows, to marry poor maids withal.

ZEAL, INDIAN CORN, in botany, a genus of the monoccia triandria class. There are three species, viz.

1. The Americana grows naturally in the islands of the West Indies, with a very large strong stalk, which rises to the height of 10 or 12 feet. The leaves are long, broad, and hang downward; they have a broad white midrib. When the seeds of this sort are ripe, the spikes or ears are nine or ten inches long, and sometimes a foot; but these rarely ripen in England.

2. The alba is cultivated in Italy, Spain, and Portugal. The stalks of this sort are slenderer than those of the former, and seldom rise more than six or seven feet high. The leaves are narrower than those of the first sort, and are hollowed like the keel of a boat, and their tops hang downwards. The grains of this sort do not come to maturity in England, unless the season proves very warm, and the grains are planted early and in a warm soil and situation.

3. The vulgare is cultivated in the northern parts of America, and also in Germany. The stalks of this are slender, and seldom rise more than four feet high. The leaves are shorter and narrower than those of the two former; they are hollowed like the keel of a boat, and their tops hang down. The spikes of male flowers are short, and the ears or spikes of grain are seldom more than four or five inches long. This sort ripens its grain perfectly well in England, in as little time as barley, so may be cultivated here to advantage.

There are several varieties of the two last species, which differ in the colour of their grain. The most common colour is that of a yellowish white; but there are some with deep yellow, others with purple, and some with blue grains; and when the different colours are planted near each other, the farina will mix, and the ears will have grains of several colours intermixed; but when the grains of the different varieties are planted at a proper distance from each other, the produce will be the same with the grains which were sown.

These plants are seldom cultivated in England.—In Italy, Germany, and in many parts of North America, they are treated in the following manner:

They first dig the ground well in the spring; and after having made it level, they draw a line across the whole piece intended to be planted; then they raise little hills at about three or four feet distance, into each of which they put two or three good seeds, covering them about an inch thick with earth; then they move the line four feet farther, continuing to do the same through the whole spot of ground, so that the rows may be four feet asunder, and the hills three or four feet distance. Six quarts of this seed is generally

allowed to an acre of land, which, if the soil be good, will commonly produce 50 bushels of corn.

When the corn is ripe, they cut off the stalks close to the ground, and after having gathered off the spikes of grain, they spread the stalks in the sun, to harden and dry, which they afterward use in the same manner as reeds in England for making fences, covering sheds, &c. for which purpose they are very useful to the inhabitants of warm countries; and when there is a scarcity of forage, they feed their cattle with them green, as fast as the corn is gathered off.

The corn is ground to flour, and the poorest sort of people in America, and also in Italy and Germany, make their bread of this flour; and in many of the warmer countries, the inhabitants roast the whole spikes, and dress them many different ways, making several dishes of it; but this grain seldom agrees with those who have not been accustomed to eat it: however, in times of scarcity of other grain, this would be a better substitute for the poor than bean-flour, or other sorts, which have been used in England, and at all times will be found a hearty food for cattle, hogs, and poultry; so that in light sandy lands, where beans and pease succeed not well, this grain may be cultivated to answer both purposes to advantage.

If this grain is cultivated by the horse-hoeing husbandry, it may be done at less expence than in any other method; for this is one of the plants which is more particularly adapted to this husbandry.

The time for sowing it is about the same as for barley.

ZEAL, the exercise of a warm animated affection, or passion, for any thing.

ZEALAND, the chief of the Danish islands, is situated at the entrance of the Baltic Sea, bounded by the Schagerrack Sea on the north; by the Sound, which separates it from Schonen, on the east; by the Baltic Sea on the south; and by the strait called the *Great Belt*, which separates it from the island of Funen, on the west; being of a round figure, near 200 miles in circumference: the chief town is Copenhagen.

ZEALAND, is also a province of the United Netherlands, consisting of eight islands, which lie in the mouth of the river Scheld, bounded by the province of Holland, from which they are separated by a narrow channel, on the north; by Brabant on the east; by Flanders, from which they are separated by one of the branches of the Scheld, on the south; and by the German ocean on the west.

NEW ZEALAND, a country of Asia, in the South Pacific Ocean, first discovered by Tasman, the Dutch navigator, in the year 1642, who gave it the name of *Staten Land*, though it has been generally distinguished in our maps and charts by the name of *New Zealand*, and was supposed to be part of a southern continent: but it is now known, from the late discoveries of Captain Cook, who sailed round it, to consist of two large islands, divided from each other by a strait four or five leagues broad. They are situated between the latitudes of 34 and 48 degrees south, and between the longitudes of 166 and 180 degrees east from Greenwich. One of these islands is for the most part mountainous, rather barren, and but thinly inhabited; but the other is much more fertile, and of a better appearance. In the opinion of Sir Joseph Banks,

Zea,
Zealand

Zealots Banks, and of Dr Solander, every kind of European fruits, grain, and plants, would flourish here in the utmost luxuriance. From the vegetables found here, it is supposed that the winters are milder than those in England, and the summers not hotter, though more equally warm; so that it is imagined, that if this country were settled by people from Europe, they would, with moderate industry, be soon supplied, not only with the necessaries, but the luxuries of life, in great abundance. Here are forests of vast extent, filled with very large timber trees; and near 400 plants were found here that had not been described by the naturalists. The inhabitants of New Zealand are stout and robust, and equal in stature to the largest Europeans. Their colour in general is brown, but in few deeper than that of the Spaniard who has been exposed to the sun, and in many not so deep; and both sexes have good features. Their dress is very uncouth, and they mark their bodies in a manner similar to the inhabitants of Otaheite, and which is called *tattooing*. Their principal weapons are lances, darts, and a kind of battle-axes; and they have generally shown themselves very hostile to the Europeans who have visited them.

ZEALOTS, an ancient sect of the Jews, so called from their pretended zeal for God's law, and the honour of religion.

ZEBRA, in zoology. See *EQUUS*.

ZECHARIAH, a canonical book of the Old Testament, containing the predictions of Zechariah, the son of Barachia, and grandson of Idolo. He is the eleventh of the 12 lesser prophets. Zechariah entered upon the prophetic office at the same time with Haggai, and was sent to the Jews upon the same message, to reprove them for their backwardness in erecting the temple and restoring divine worship; but especially for the disorder of their lives and manners, which could not but derive a curse upon them. By several notable visions and types, he endeavours to confirm their faith, and establish their assurance concerning God's providence with them, and care over them; and as a proof and demonstration of this, he interperes the most comfortable promises of the coming of the kingdom, the temple, the priesthood, the victory, the glory of Christ the Branch. Nor does he forget to assure them of the ruin of Babylon, their most implacable enemy. This prophet is the longest and most obscure of all the lesser prophets, his style being interrupted and without connection.

ZEDOARY, in the materia medica, a root, the several pieces of which differ so much from one another in shape, that they have been divided into two kinds, as if two different things, under the names of the *long* and *round* zedoary, being only the several parts of the same root.

Zedoary is to be chosen fresh, sound, and hard, in large pieces; it matters not as to shape, whether long or round; of a smooth surface, and of a sort of fatty appearance within, too hard to be bitten by the teeth, and of the briskest smell that may be: such as is friable, dusty, and worm eaten, is to be rejected.

Zedoary, both of the long and round kind, is brought us from China; and we find by the Arabians that they also had it from the same place. The round tubera are less frequent than the long, and some of them

have therefore supposed them the produce of a different and more rare plant; but this is not so probable as that the general form of the root is long, and the round tubera are only *lusus naturæ*, and less frequent in it.

Zedoary, distilled with common water, affords a thick and dense essential oil, which soon concretes of itself into a kind of camphor; and on this oil its virtues principally depend. It is a sudorific, and is much recommended by some in fevers, especially of the malignant kinds. It is also given with success as an expectorant in all disorders of the breast, arising from a tough phlegm, which it powerfully incises and attenuates; it is also good against flatulences, and in the choleric; it strengthens the stomach, and assists digestion; and finally, is given with success in nervous cases of all kinds.

ZELL, a city of Germany, in the circle of Lower Saxony, capital of the duchies of Zell and Lunenburg, situated at the confluence of the rivers Ailer and Fuhle, 30 miles north of Hanover, and 40 south of Lunenburg. E. Long. 10. N. Lat. 52. 52.

ZEND, or **ZENDAVESTA**, a book containing the religion of the Magians, or worshippers of fire, who were disciples of the famous Zoroaster. See *MAGI*.

This book was composed by Zoroaster during his retirement in a cave, and contained all the pretended revelations of that impostor. The first part contains the liturgy of the Magi, which is used among them in all their oratories and fire-temples to this day; they reverence it as the Christians do the Bible, and the Mahometans the Alcoran. There are found many things in the Zend taken out of the scriptures of the Old Testament, which Dr Prideaux thinks is an argument that Zoroaster was originally a Jew. Great part of the Psalms of David are inserted: he makes Adam and Eve to have been the first parents of mankind, and gives the same history of the creation and deluge as Moses does, and commands the same observances about clean and unclean beasts, the same law of paying tithes to the sacerdotal order, with many other institutions of Jewish extraction. The rest of its contents are an historical account of the life, actions, and prophecies of its author, with rules and exhortations to moral living. The Mahometans have a sect which they call *Zendikites*, who are said to be the Sadducees of Mahometanism, denying providence and the resurrection, believing the transmigration of souls, and following the Zend of the Magi.

ZENITH, in astronomy, the vertical point; or a point in the heavens directly over our heads.

ZENO ELEATES, or of *Elea*, one of the greatest philosophers among the ancients, flourished about the 504th year before the Christian æra. He was the disciple of Parmenides, and even, according to some writers, his adopted son. Aristotle asserts, that he was the inventor of logic; but his logic seems to have been calculated to perplex all things, and not to clear up any thing. For Zeno employed it only to dispute against all comers, and to silence his opponents, whether they argued right or wrong. He proposed very embarrassing arguments with respect to the existence of motion; and Aristotle, in the sixth book of his *Physics*, has preserved some of them, which are extremely subtle, especially the famous argument named *Achilles*.

Zeno
II
Zephaniah.

Zephyrus
I
Zeus.

As he lived long before Diogenes the Cynic, it is certain that those who have said that this last philosopher refuted Zeno's arguments against motion, by taking a turn or two up and down his school, are mistaken. He flew into a violent passion with a man who railed at him; and it being thought strange that he should feel such indignation, he replied, "Were I insensible to censure, I should be equally so with respect to praise." He showed great courage in suffering pain; for having undertaken to restore liberty to his country, which groaned under the oppression of a tyrant, and the enterprise being discovered, he supported with extraordinary firmness the sharpest torments. It is said that he had the courage to bite off his tongue, and spit in the tyrant's face, for fear of being forced, by the violence of his torments, to discover his accomplices. Some say that he was pounded alive in a mortar.

ZENO, a celebrated Greek philosopher, was born at Citium, in the isle of Cyprus, and was the founder of the sect of the Stoics. This sect had its name from that of a portico at Athens, where this philosopher chose to hold his discourses. He was cast upon that coast by shipwreck; and he ever after regarded this as a great happiness, praising the winds for having so happily driven him into the port of Piræum. Zeno was the disciple of Crates, and had a great number of followers. He made the sovereign good consist in living in conformity to nature, guided by the dictates of right reason. He acknowledged but one God; and admitted an inevitable destiny over all events. His servant taking advantage of this last opinion, cried, while he was beating him for his dishonesty, "I was destined to steal." To which Zeno replied, "Yes; and to be beaten." This philosopher was accustomed to say, "That if a wife man ought not to be in love, as some pretended, none would be more miserable than beautiful and virtuous women, since they would have none for their admirers but fools." He also said, "That a part of knowledge consists of being ignorant of such things as ought not to be known: that a friend is another self; that a little matter gives perfection to a work, though perfection is not a little matter." He compared those who spoke well and lived ill, to the money of Alexandria, which was beautiful, but composed of bad metal. It is said, that being hurt by a fall, he laid violent hands on himself about 264 B. C. Cleanthes, Cryppus, and the other successors of Zeno maintained, that with virtue we might be happy in the midst even of disgrace and the most dreadful torments. They admitted the existence of only one God, the soul of the world, which they considered as his body, and both together forming a perfect being. It must be confessed, that of all the sects of the ancient philosophers, this was one of those which produced the greatest men.

We ought not to confound the two Zenos already mentioned, with

ZENO a celebrated Epicurean philosopher, born at Sidon, who had Cicero and Pomponius Atticus for his disciples, and who wrote a book against the mathematics, which, as well as that of Posidonius's refutation of it, is lost; nor with several other Zenos mentioned in history.

ZENOBIA, queen of Palmyra. See PALMYRA.

ZEPHANIAH, a canonical book of the Old Te-

stament, containing the predictions of Zephaniah the son of Cushi, and grandson of Gedaliah; being the ninth of the 12 lesser prophets. He prophesied in the time of king Josiah, a little after the captivity of the ten tribes, and before that of Judah; so that he was cotemporary with Jeremiah. He freely publishes to the Jews, that what increased the divine wrath against them, was their contempt of God's service, their apostasy, their treachery, their idolatry, their violence and rapine, and other enormities: such high provocations as these, rendered their destruction terrible, universal, and unavoidable; and then, as most of the prophets do, he mingles exhortations with repentance, as the only expedient in these circumstances.

ZEPHYR, the *West-Wind*, or that which blows from the cardinal point of the horizon opposite to the east.

ZEPHYRUS, one of the pagan deities, was represented as the son of Aurora, and the lover of the nymph Chloris, according to the Greeks, or of Flora, according to the Romans; and as presiding over the growth of fruits and flowers. He is described as giving a refreshing coolness to the air by his soft and agreeable breath, and as moderating the heat of summer by fanning the air with his silken wings. He is depicted under the form of a youth, with a very tender air, with wings resembling those of the butterfly, and with his head crowned with a variety of flowers. As the poets of Greece and Rome lived in a warm climate, they are lavish in the praise of this beneficent deity, and under his name describe the pleasure and advantage they received from the western breezes.

ZEST, the woody thick skin, quartering the kernel of a walnut; prescribed by some physicians, when dried and taken with white wine, as a remedy against the gravel.

Zest is also used for a chip of orange or lemon peel; such as is usually squeezed into ale, wine, &c. to give it a flavour; or the fine ethereal oil which spurts out of that peel on squeezing it.

ZEUGMA, a figure in grammar, whereby an adjective or verb which agrees with a nearer word, is also, by way of supplement, referred to another more remote.

ZEUS, in ichthyology, a genus belonging to the order of thoracici. The head is compressed, and declines, the upper lip being vaulted over by a transverse membrane; the tongue is subulated; there are seven rays in the gill membrane; and the body is compressed.—The species are four; of which the most remarkable is the faber, or dore. It is of a hideous form, its body is oval, and greatly compressed on the sides; the head large; the snout vastly projecting; the mouth very wide; the teeth very small; the eyes great, the irides yellow; the lateral line oddly distorted, sinking at each end, and rising near the back in the middle; beneath it on each side is a round black spot. The tail is round at the end, and consists of 15 branched rays. The colour of the sides is olive, varied with light blue and white, and while living is very resplendent, and as if gilt; for which reason it is called the *dore*. The largest fish we have heard of weighed 12 pounds.

Superstition hath made the doree rival to the had-dock, for the honour of having been the fish out of whose mouth St Peter took the tribute-money, leaving en

on its sides those incontestible proofs of the identity of the fish, the marks of his finger and thumb. It is rather difficult at this time to determine on which part to decide the dispute; for the doree likewise asserts an origin of its spots of a similar nature, but of a much earlier date than the former. St Christopher, in wading through an arm of the sea, having caught a fish of this kind *en passant*, as an eternal memorial of the fact, left the impressions on its sides to be transmitted to all posterity. In our own country it was very long before this fish attracted our notice, at least as an edible one. We are indebted to the late Mr Quin for adding a most delicious fish to our table, who overcoming all the vulgar prejudices on account of its deformity, has effectually established its reputation. This fish was supposed to be found only in the southern seas of this kingdom, but it has been discovered last year on the coast of Anglesea. Those of the greatest size are taken in the Bay of Biscay, off the French coasts; they are also very common in the Mediterranean: Ovid must therefore have styled it *rarus faber*, on account of its excellency, not its scarcity.

ZEUXIS, a celebrated painter of antiquity, flourished about 400 years before Christ. He was born at Heraclea; but as there have been many cities of that name, it cannot be certainly determined which of them had the honour of his birth. Some learned men however conjecture, that it was the Heraclea near Crotona in Italy. He carried painting to a much higher degree of perfection than Apollodorus had left it; discovered the art of properly disposing of lights and shades, and particularly excelled in colouring. He amassed immense riches; and then resolved to sell no more of his pictures, but gave them away; saying very frankly, "That he could not set a price on them equal to their value." Before this time he made people pay for seeing them; and nobody was admitted to see his Helena without ready money, which occasioned the wags calling his picture *Helena the Courtesan*. It is not known whether this Helen of Zeuxis was the same with that which was at Rome in Pliny's time, or that which he painted for the inhabitants of Crotona to be hung up in the temple of Juno: this last he painted from five beautiful girls of that city, copying from each her greatest excellencies. Pliny observes, that this admirable painter, disputing for the prize of painting with Parrhasius, painted some grapes so naturally, that the birds flew down to peck them. Parrhasius, on the other hand, painted a curtain so very artfully, that Zeuxis mistaking it for a real one that hid his rival's work, ordered the curtain to be drawn aside, to show what Parrhasius had done; but having found his mistake, he ingenuously confessed himself vanquished, since he had only imposed upon birds, while Parrhasius had deceived even a master of the art. Another time he painted a boy loaded with grapes; when the birds also flew to this picture, at which he was vexed; and confessed, that this work was not sufficiently finished, since had he painted the boy as perfectly as the grapes, the birds would have been afraid of him. Archelaus, king of Macedonia, made use of Zeuxis's pencil for the embellishment of his palace. One of this painter's finest pieces was a Hercules struggling some serpents in his cradle, in the presence of his affrighted mother: but he himself chiefly esteemed his *Athleta*, or Champion,

under which he placed a Greek verse that afterwards became very famous, and in which he says, "That it was easier to criticise than to imitate the picture." He made a present of his Alcmena to the Agrigenines. Zeuxis did not value himself on speedily finishing his pictures; but knowing that Agatharchus gloried in his being able to paint with ease and in a little time, he said, "That for his part he, on the contrary, gloried in his slowness; and if he was long in painting, it was because he painted for eternity." Verrius Flaccus says, that Zeuxis having painted an old woman, he laughed so very heartily at the sight of this picture, that he died: but as no other of the ancients have mentioned this particular, there is the greatest reason to believe it fabulous. Carlo Dati has composed in Italian the Life of Zeuxis, with those of Parrhasius, Apelles, and Protogenes. This work was printed at Florence in 1667.

ZICLAG, or ZIKLAG (anc. geog.), a town of the tribe of Simeon, on the borders of the Philistines, (Joshua xv. and xix.), but in the hands of the Philistines till David's time, (1 Sam. xxvii. and xxx.)

ZIN (anc. geog.), a wilderness encompassing Idumea, at least on the south and west, as far as Palestine or Canaan; but according to Wells, on the east of Edom, to the north of Ezion-gaber.

ZINC. See CHEMISTRY, p. 1864, *feA*. iii. 8.; *MATERIA MEDICA, Catalogue of Simple*; and *PHARMACY*, n° 798—801.

It is remarkable that this semi-metal, when united with copper even in a considerable proportion, diminishes very little the malleability of that metal, and at the same time renders its colour more beautiful, and more like the colour of gold. This colour varies according to the different proportions of these two metallic substances in the compound, which acquires different names accordingly, as brass, tombac, similor, pinchbeck, and prunee's metal. The zinc for these compositions must be very pure, and free from other metallic bodies. The method of purifying this semi-metal, which is principally founded upon its property of not uniting with sulphur, is thus described by Mr Macquer:—"When zinc is melted in a large crucible, suet and sulphur alternately, and the latter in larger quantities than the former, must be thrown upon it. If the zinc is pure, the sulphur burns freely on its surface; but if it is alloyed, the sulphur combines with the other metals, and forms with them a kind of scoria, which must be taken off. This alternate projection of suet and sulphur upon zinc is continued till the sulphur be burnt on the surface of the melted zinc without forming any scoria; the zinc thus purified, may be successfully employed for making of brass or metallic mixtures in imitation of gold.

ZINZENDORFF (Nicholas Lewis), count, was the noted founder of the German religious sect called *Moravians*, or *Herrnhuters*. From his own narrative it appears, that when he came of age in 1721, his thoughts were wholly bent on gathering together a little society of believers, among whom he might live, and who should entirely employ themselves in exercises of devotion under him. He accordingly purchased an estate at Bertholdsdorf in Upper Lusatia, where being joined by some followers, he gave the curacy of the village to a man of his own complexion; and Bertholdsdorf

dorff soon became talked of for a new mode of piety. One Christian David, a carpenter, brought a few profelytes from Moravia; they began a new town about half a league from the village, where count Zinzendorf fixed his residence among them, and where great numbers of Moravians flocked and established themselves under his protection: so that in 1732 their number amounted to 600. An adjacent hill, called the *Huthberg*, gave occasion to these colonists to call their new settlement *Huth des Herrn*, and afterward *Herrnhuth*; which may be interpreted "The guard or protection of the Lord;" and from this the whole sect have taken their name. The count spared neither pains nor art to propagate his opinions; he went himself all over Europe, and at least twice to America; and sent his missionaries throughout the world. In 1733 a Herrnhut was established even in Greenland; the society possesses Bethlehem in Pennsylvania, and has a settlement among the Hottentots: China, it is reported, has admitted them; and we know what progress they have made in our own country as well as on the continent. Their discipline is very rigid, and therefore submission to the will of their superiors is inculcated as the will of their Saviour: hence the language they talk in is, "Jesus will have it so; the Lamb commands it;" a language not uncommon in the mouth of spiritual taskmasters. As to the doctrine taught by the Moravians, it may be observed, that enthusiastic devotees in all ages, have been apt to suffer their heavenly affections to stray down to carnal objects; but it was reserved for count Zinzendorf to frame a religious system upon obscene principles. Thus he says, "What is called in the Bible by the hideous name *pendulum*, or a thing to be ashamed of on account of the fall, is changed by the Saviour into *verendum*, or a thing to be worshipped." "I consider (says he) the parts for distinguishing both sexes in Christians, as the most honourable of the whole body, my Lord and God having partly inhabited them and partly worn them himself." In conformity to these ideas, he and his followers esteem the conjugal embrace as the highest act of devotion. "Jesus (we are told) is the spouse of all the filters; the husbands, in the proper sense, are his procurators or agents, and may therefore be called *vice christi*, or *vice gods*: all souls are of the feminine gender; the male quality adapted to bodies at their formation being detached as soon as it is interred." Their discourses and hymns contain a deal of nonsense about the five wounds of Christ; particularly the side hole. Count Zinzendorf died in 1760. Those who wish to know more of the Moravian tenets may consult Rimius's account of them, translated in 1753.

ZISCA (John), a famous general of the forces of the Hussites, in the 15th century, was a gentleman educated at the court of Bohemia, in the reign of Wenceslaus. He entered very young into the army, and after distinguishing himself on several occasions, lost an eye in a battle, whence he was called *Zisca*, or *One-eyed*. At length the Reformation, begun by John Hus, spreading through almost all Bohemia, Zisca placed himself at the head of the Hussites, and had soon under his command a body of 40,000 men. With this army he gained several victories over those of the Romish religion, who carried on a kind of crusade against them; and built a town in an advantageous situation,

to which he gave the name of *Tabor*; whence the Hussites were afterwards called *Taborites*. Zisca lost his other eye by an arrow at the siege of the city of Rabi; but this did not prevent his continuing the war, his fighting battles, and gaining several great victories, among which was that of Aulig on the Elbe, in which 9000 of the enemy were left dead on the field. The emperor Sigismund, alarmed at his progress, caused very advantageous proposals to be offered to him; which he readily accepted, and set out to meet Sigismund, but died on the road. He ordered that his body should be left a prey to the birds and wild beasts; and that a drum should be made of his skin, being persuaded that the enemy would fly as soon as they heard its sound. It is added, that the Hussites executed his will; and that the news of this order made such an impression on the disturbed imaginations of the German Papists, that in many battles they actually fled at the beat of the drum with the utmost precipitation, leaving their baggage and artillery behind them.

ZINZIBER, or ZINGIBER, in botany. See *AMOMUM* and *GINGER*.

ZION, or SION (anc. geog.), a very famous mountain, standing on the north side of the city of Jerusalem, (Pal. xlviii. 2.); containing the upper city, built by king David; and where stood the royal palace, (Josephus). A part of Zion, situate at its extremity, was called *Millo*, or, in the city of David, (2 Chron xxxii. 5.) Modern travellers, who have been upon the spot, say, that Zion is the whole of the mountain, on which Jerusalem stands at this day, though not to the extent in which it anciently stood on the same mountain, as appears Pal. ix. 12. 15. lxxv. l. lxxxvii. 2, 3. If. lxii. 1. swelled into several eminences or tops; as Moriah, Acra Bezetha, and Zion, a particular eminence of mount Zion Proper, &c. encompassed on three sides, east, west, and south, with one continued very deep and steep valley; by means of which it was impregnable on these three sides, and always attacked and taken, according to Josephus, by the enemy on the north side, where mount Zion becomes level, and the vales of Gihon and Jehosaphat gradually lose themselves. This deep and steep valley incontestibly constitutes the compass of the old Jerusalem on those three sides, as plainly appears to any person who has been upon the spot. On that particular top of the mount called *Zion*, stood the fortrefs of the Jebusites; which being afterwards taken by David, came to be called the *city of David*, where he had his royal residence, and kept his court. That part of the valley which lay to the east was called *Jehosaphat's*, having mount Olivet lying beyond it; that to the south, *Gebinnon*; and that to the west, *Gihon*, from cognominal mountains lying beyond them. At the west end of Gihon, without the city, stood Golgotha or Calvary. The pretended Golgotha, shown at this day within the walls, is the spurious brat of interested and fraudulent monks, (Korie). There is another Zion, the same with HEBMON.

ZIPH, or SIPH (anc. geog.), the name of a wilderness or desert in the tribe of Judah, where David was a fugitive; lying to the south-east of Hebron; so called from Ziph or Siph, a twofold town in this tribe; the one more to the south towards Idumea, on the confines of Eleutheropolis, (Jerome); the other 8 miles

chnitzer. to the east of Hebron, towards the Dead Sea, inclining southwards, because near mount Carmel. Here was a mountain, mentioned 1 Sam. xxiii. 14. in which David abode, said by Jerome to be rugged, dismal, and always overcast. *Ziphim, Ziphlei, or Ziphenses*, the inhabitants of Ziph, ver. 19.

ZIRCHNITZER, *see*, otherwise called the *lake of Czirknitz*, in Carniola, is about one German or four English miles in length, and half as much in breadth, contains three beautiful islands, and is encompassed at some distance with mountains and forests. But what is most remarkable is, that it disappears generally once a-year, about St John or St James's day, running off through holes or pits in the bottom; sometimes it will disappear twice or thrice a-year, and sometimes even in winter, if the weather be dry. On the other hand, it has been known to continue two or three years without running off. Of the holes or pits, there are five much larger than the rest, each of which successively, when the water runs off, stands empty five days; so that the whole lake becomes dry in 25. As soon as the beginning of the ebb is observed, the fishing in the pits begins, which belong to five seigniories. The fish, which are carp, tench, pike, eels, and two other sorts, called *schleien* and *ruten*, are caught by laying nets over the holes. Mr Keyser tells us, that upon the ringing of a bell at Zirknitz, when the waters begin to fall, the peasants, both men and women, run to the pools quite naked, notwithstanding both the clergy and magistrates have used their utmost endeavours to suppress so indecent a custom. When the water runs off early in the year, in about three weeks after it is gone there is good grass on the bottom, which is mowed down, and the bottom afterwards ploughed, and sowed with millet. If the water runs not off early, nothing can be sown; and if it returns soon, the seed is lost. With respect to its return, the water at first bursts out of some pits on the south side with great violence, a little rain always falling at the same time; but after-

wards (when the rain falls heavier, and it thunders at the same time so loud as to shake the earth) it breaks out through all the apertures with great force, inasmuch that the lake is filled in 18 or 24 hours, at which time it is in a manner covered with wild fowl; such as geese, ducks, &c. After the millet-harvest, all manner of game is hunted, caught, or killed in it. On the south side are two caverns, out of which, when it thunders, water issues with astonishing violence; and if it happens in harvest, a great many naked, black, and blind, but fat ducklings, are brought up with the water, which in 14 days receive their sight, and are covered with feathers.

ZODIAC, in astronomy, a fascia, or broad circle, whose middle is the ecliptic, and its extremes two circles parallel thereto, at such a distance from it as to bound or comprehend the excursions of the sun and planets. *See* **ASTRONOMY**, n° 204.

ZODIACAL LIGHT. *See* **AURORA Borealis**.

ZONE, in geography and astronomy, a division of the terraqueous globe with respect to the different degrees of heat found in the different parts thereof.

A zone is the fifth part of the surface of the earth, contained between two parallels.

The zones are denominated torrid, frigid, and temperate.

The torrid zone is a fascia, or band, surrounding the terraqueous globe, and terminated by the two tropics. Its breadth is 46. 58. The equator, running through the middle of it, divides it into two equal parts, each containing 23. 29. The ancients imagined the torrid zone uninhabitable.

The temperate zones are two fasciæ, or bands, environing the globe, and contained between the tropics and the polar circles. The breadth of each is 43. 2.

The frigid zones are segments of the surface of the earth, terminated, one by the antarctic, and the other by the arctic circle. The breadth of each is 46. 58.

Z O O L O G Y

Mammalia. **I**S that part of Natural History which relates to *Animals*. It is necessary to mention in this place, that we have given the descriptions and characters of animals under their proper names. The scientific part of the subject, therefore, or the method of investigating the genera or species of animals, by means of natural or artificial arrangement, only remains to be explained.

In order to abridge the study of zoology, many methods of reducing animals to classes, genera, and species, have been invented. But as that of Linnæus is undoubtedly the best, the most extensive, and the most generally adopted, we shall give a brief account of it.

Linnæus divides the whole animal kingdom into six classes. The characters of these six classes are taken from the internal structure of animals, in the following manner:

CLASS I. MAMMALIA, includes all animals that suckle their young. The characters of this class are these:—The heart has two ventricles and two auricles; the blood is red and

warm; and the animals belonging to it are *Mammalia*, *viviparous*.

CLASS II. AVES, or BIRDS. The characters are the same with those of Class I. excepting that the animals belonging to it are *oviparous*. *See* **BIRD**, and **ORNITHOLOGY**.

CLASS III. AMPHIBIA, or AMPHIBIOUS ANIMALS. The heart has but one ventricle and one auricle; the blood is red and cold; and the animals belonging to this class have the command of their *lungs*, so that the intervals between *inspiration* and *expiration* are in some measure *voluntary*. *See* **AMPHIBIOUS**.

CLASS IV. PISCES, or FISHES. The heart has the same structure, and the blood the same qualities with those of the *Amphibia*; but the animals belonging to this class are easily distinguished from the *Amphibia*, by having no such voluntary command of their *lungs*, and by having external *branchiæ* or *gills*. *See* **FISH**.

CLASS V. INSECTA, or INSECTS. The heart has one ventricle, but no auricle; the blood is cold

cold and white; and the animals are furnished with *antennæ* or *feelers*. See INSECT.

CLASS VI. VERMES, or WORMS. The characters are the same with those of Class V. only the animals have no antennæ, and are furnished with *tentaculo*.

The *First Class*, MAMMALIA, is subdivided into seven ORDERS; the characters of which are taken from the number, structure, and situation of the TEETH.

ORDER I. The PRIMATES have four incisors, or *fore-teeth*, in each jaw, and one *dog tooth*.

N. B. By one dog-tooth, Linnæus means one on each side of the *fore-teeth* in both jaws.—This order includes four genera, viz. Homo, Simia, Lemur, Vespertilio. See these articles.

ORDER II. The BRUTA have no *fore-teeth* in either jaw. This order includes six genera, viz. Elephas, Trichechus, Bradypus, Myrmecophaga, Manis, Dasypus. See these articles.

ORDER III. The FERÆ have, for the most part, six *conical fore-teeth* in each jaw. This order includes 10 genera, viz. Phoca, Canis, Felis, Viverra, Mustela, Ursus, Didelphus, Talpa, Sorex, Erinaceus. See these articles.

ORDER IV. The GLIRES, have two *fore-teeth* in each jaw, and no *dog-teeth*—This order includes 6 genera, viz. Hytrix, Lepus, Castor, Mus, Sciurus, Noctilio. See these articles.

ORDER V. The PECORA, have no *fore-teeth* in the upper jaw, but 6 or 8 in the under-jaw.—This order includes 6 genera, viz. Camelus, Moschus, Cervus, Capra, Ovis, Bos. See these articles.

ORDER VI. The BELLUÆ, have *obtuse fore-teeth* in each jaw.—This order includes 4 genera, viz. Equus, Hippopotamus, Sus, Rhinoceros. See these articles.

ORDER VII. The CETÆ, or *whale kind*, have no uniform character in their teeth, being very different in the different genera; but are sufficiently distinguished from the other orders of Mammalia, by living in the ocean, having pectoral fins, and a siphula or spiraculum upon the head.—This order includes 4 genera, viz. Monodon, Balæna, Phylæter, Delphinus. See these articles, and CETACEOUS.

The *generic* characters of the Mammalia are, like those of the orders, almost entirely taken from the TEETH, excepting the Vespertilio, which, besides the character of the order derived from the teeth, has this farther mark, that there is a membrane attached to the feet and sides, by means of which the creature is enabled to fly;—the Hytrix, whose body is covered with sharp spines;—and the whole order of Pecora, whose genera, besides the characters taken from the teeth, are distinguished into those which have *horns*, those which have *no horns*, and by peculiarities in the horns themselves.

The *specific* characters are very various, being taken from any part of the body which possesses a peculiar uniform mark of distinction. As examples of these characters are to be found under the proper name of

each genus; it is unnecessary to say any thing further concerning them in this place.

The *Second Class*, AVES, is subdivided into six ORDERS, the characters of which are taken chiefly from the structure of the BILL.

ORDER I. The ACCIPITRES, have a HOOKED BILL, the superior mandible, near the base being extended on each side beyond the inferior; and in some, the superior mandible is armed with *teeth*.—This order includes 4 species, viz. Vultur, Falco, Strix, Lanius. See these articles.

ORDER II. The PICÆ, have a convex, compressed BILL, resembling a knife.—This order contains 22 genera, viz. Buphaga, Certhia, Corvus, Cuculus, &c. See these articles.

ORDER III. The ANSERES, have an obtuse BILL, gibbous at the base, broadest at the point, covered with a smooth skin, and furnished with teeth: The *tongue* is fleshy; and the toes are palmated, or webbed.—This order includes 12 genera, viz. Alca, Anas, Colymbus, Diomedea, &c. See these articles.

ORDER IV. The GRALLÆ, have a long, obtuse, and somewhat cylindrical BILL: The *tongue* is undivided, and fleshy; and the *thighs* are naked. This order contains 18 genera, viz. Ardea, Fulica, Tringa, Charadrius, &c. See these articles.

ORDER V. The GALLINÆ, have a convex BILL; the superior mandible is vaulted over the inferior, and the margin of the superior mandible folds over the inferior one: The *nostrils* are half covered with a convex cartilaginous membrane: The *rectrices*, or principal quill-feathers of the tail, are always more than 12 in number; and the *feet* are divided, but connected at the innominate joint.—This order contains 7 genera, viz. Didas, Puffinus, Meleagris, Pavo, &c. See these articles.

ORDER VI. The PASSERES, have a conical sharp-pointed BILL; and the *nostrils* are oval, wide, and naked.—This order contains 15 genera, viz. Caprimulgus, Alauda, Calumba, &c. See these articles.

The *generic* characters of this class are taken from peculiarities in the *bill*, the *nostrils*, the *tongue*, the *feet*, the *feathers*, the *face*, the *figure of the body*, &c.

The characters which serve to distinguish the *species* are very various: For example, the *colour of particular feathers* or parts of *feathers*; *crests* of feathers on the head, disposed in different manners; the *colour of the cere* or *wax*; the *colour of the feet*; the *shape and length of the tail*; the *number, situation, &c. of the toes*; the *colour and figure of the bill*; &c.

The *Third Class*, AMPHIBIA, is divided into four ORDERS.

ORDER I. The REPTILES, have *legs*, and breathe by the *mouth*.—This order contains 4 genera, viz. Testudo, Draco, Lacerta, Rana. See these articles.

ORDER II. The SERPENTES, have no *legs*, and breathe

breathe by the *mouth*.—This order contains 6 genera, *viz.* Crotalus, Boa, Coluber, Anguis, Amphisbæna, Cæcilia. See these articles.

ORDER III. The NANTES, are furnished with *lungs*, and at the same time breathe by lateral *gills*; and the rays of their fins are cartilaginous.—This order contains 14 genera, *viz.* Accipenser, Balistes, &c. See these articles.

ORDER IV. The MEANTES, have both *lungs* and *gills*; and the *feet* are furnished with *toes* and *claws*.—This order contains but one genus, *viz.* the Siren. See SIREN.

The *generic* characters of this class are taken from the general figure of the *body*; from their having *tails* or *no tails*; being covered with a *shell*; having *teeth*, or *no teeth*, in the *mouth*; being furnished with *wings*; having *covered* or *naked* bodies; from the number, situation, and figure of the *scuta* and *scales*; from the number and situation of the *spiracula*; from the situation of the *mouth*, &c.

The *specific* characters are so very various, that it would be superfluous to enumerate them.

The *Fourth Class*, PISCES, is subdivided into four ORDERS, the characters of which are taken from the situation of the *belly-fins*.

ORDER I. The APODES, have *no belly-fins*.—This order contains 8 genera, *viz.* Ammodytes, Anarrhicas, Muræna, &c. See these articles.

ORDER II. The JUGULARES, have the *belly-fins* placed before the *pectoral fins*.—This order includes 5 genera, *viz.* Callionymus, Blennius, Gadus, &c. See these articles.

ORDER III. The THORACICI, have the *belly-fins* placed under the *pectoral fins*.—This order comprehends 17 genera, *viz.* Gobius, Labrus, Sparus, &c. See these articles.

ORDER IV. The ABDOMINALES, have the *belly-fins* placed behind the *pectoral fins*.—This order contains 17 genera, *viz.* Fistularia, Efox, Clupea, Cyprinus, &c. See these articles.

The *generic* characters of this class are taken from peculiarities in the *head*, the *mouth*, the *teeth*, the *nostrils*, the *rays* in the *membrane of the gills*, the *eyes*, the general figure of the *body*, the figure of the *tail*, the situation of the *spiracula*, &c.

The *specific* characters are taken from peculiarities in all the parts above enumerated, and many others.

See further the articles FISH in *Encycl.* and ICHTHOLOGY in the APPENDIX.

The *Fifth Class*, INSECTA, is subdivided into 7 ORDERS, the characters of which are taken from the wings. See the article INSECT.

ORDER I. The COLEOPTERA, have *four wings*, the two superior ones being *crucaceous*, and furnished with a *straight suture*.—This order comprehends 40 genera, *viz.* Attelabus, Scarabæus, Coccinella, Melœ, &c. See these articles.

ORDER II. The HEMIPTERA have *four wings*, the two superior ones being *semicrucaceous*, and *incumbent*, i. e. the *interior edges* lie above one another.—This order includes 12 genera, *viz.* Blatta, Gryllus, Cicada, &c. See these articles.

ORDER III. The LEPIDOPTERA, have *four wings*, all of them imbricated with *scales*.—This order contains 3 genera, *viz.* Papilio, Sphinx, Phalæna. See these articles.

ORDER IV. The NEUROPTERA, have *four wings*, interwoven with veins, like a piece of *network*, and *no suture* in the *anus*.—This order includes 7 genera, *viz.* Libella, Ephemera, Hemerobius, &c. See these articles.

ORDER V. The HYMENOPTERA, have the same characters with the former, only the *anus* is armed with a *sing.* But this mark is peculiar to the *females* and *neuters*; for the *males* have *no suture*.—This order comprehends 10 genera, *viz.* Apis, Formica, Vespa, &c. See these articles.

ORDER VI. The DIPTERA, have *two wings*, and two *clavated balancers* or *balances* behind each wing.—This order contains 10 genera, *viz.* Bombylius, Atilus, Tipula, &c. See these articles.

ORDER VII. The APTERA, have *no wings*. This order contains 14 species, *viz.* Acarus, Aranea, Pediculus, &c. See these articles.

See further the article INSECT in the *Encycl.* and the articles ENTOMOLOGY and INSECT in APPENDIX.

The *Sixth Class*, VERMES, is divided into five ORDERS.

ORDER I. The INTESTINA, are the most *simple animals*, being perfectly *naked*, and without *limbs* of any kind.—This order contains 7 genera, *viz.* Lumbricus, Spinunculus, Fasciola, Gordius, Ascaris, Hirudo, Mycine. See these articles.

ORDER II. The MOLLUSCA, are likewise *simple naked animals*, without any *shell*; but they are *brachiated*, or furnished with a kind of *limbs*.—This order comprehends 18 genera, *viz.* Afcidia, Limax, Doris, Tethys, Aphrodita, Sepia, &c. See these articles.

ORDER III. The TESTACEA, have the same characters with those of Order II. but are covered with a *shell*.—This order includes 39 genera, *viz.* Anomia, Cardium, Argonauta, Bulla, Buccinum, &c.

ORDER IV. The LITHOPHYTA, are *compound animals*, fixed upon a *calcareous base* constructed by the creatures *themselves*.—This order includes the corals, of which there are 4 genera, *viz.* Tubipora, Madrepora, &c. See these articles.

ORDER V. The ZOOPHYTA, are *compound animals*, furnished with a kind of *flowers*, and having a *vegetating root and stem*.—This order contains 15 genera, *viz.* Spongia, Gorgonia, Tubularia, Hydra, &c. See these articles.

This short explanation will enable any person who understands the Latin language to peruse the *Sytlema Naturæ* of Linnæus without the assistance of a master.—For more particular information concerning the several branches and subjects of zoology, he may consult the various articles above referred to.

ZOOPHYTE, in natural history, a kind of intermediate body partaking of the nature of a sensitive and a vegetable. See **ZOOLOGY**.

ZOOTOMY, the art of dissecting animals or living creatures, being the same with anatomy. See **ANATOMY**, and **COMPARATIVE ANATOMY**.

ZOROASTER, or **ZERDUSHT**, a celebrated Persian philosopher, said to have been the reformer of the religion of the magi, and to have lived in the reign of Darius Hystaspes. Others place him above 500 years before that æra : in short, authors differ so much with respect to him, that nothing certain can be affirmed on the subject.

ZOSIMUS, an ancient historian who lived at the end of the fourth and beginning of the fifth centuries. There are six books of his history extant ; in the first of which he runs over the Roman affairs in a very succinct manner from Augustus to Dioclesian ; the other five are written more diffusively. Zosimus was a zealous Pagan ; whence we find him frequently inveighing with great bitterness against the Christian princes, particularly against Constantine the Great, and the elder Theodosius. His history has been published with the Latin version of Leunclavius at Frankfort, 1590, with the other minor historians of Rome, in folio ; and at Oxford in 8vo. 1679.

ZUCCHERO (Taddeo), an Italian painter, born in the duchy of Urbino in 1529, was initiated in the art by his father, an ordinary painter ; but at the age of 14 was placed at Rome under Pietro Calabro. He excelled in a florid invention, and a genteel manner of designing ; but was not much admired for his colouring, which rather resembled that of statues than the life. He left many pieces unfinished, being snatched away in his prime in 1566.

ZUCCHERO (Frederico), an eminent painter, the brother of Taddeo, was born in 1543 ; and being carried to the jubilee at Rome in 1550, was placed under his brother there. He afterwards finished many of his brother's pieces. Pope Gregory XIII. employed him ; but having a difference with some of his officers, he drew a picture of Slander, that was afterward engraved by Cornelius Cort, in which he represented those who had offended him, decorated with asses ears. For this he was obliged to leave Rome ; he then worked in France for the cardinal of Lorraine, and in the Escorial for Philip II. without contenting either of them ; but was more fortunate in England, where he drew a picture of queen Elizabeth, and did some other pieces that were much commended. At length returning to Italy, and working at Venice, pope Gregory recalled and pardoned him. Soon after he received a brief from the pope for erecting an academy of painting ; of which being chosen the first prince, he built a noble apartment for their meeting. He afterwards went to Venice, to print some books he had written on painting, and from thence passed into Savoy ; but in a journey to Loretto died at Ancona, in the year 1609. In his style and manner of painting, he differed but little from his brother, though he far excelled him in sculpture and architecture.

ZUG, a canton of Switzerland, bounded on the east and north by that of Zurich, on the south by Schweiz and Lucern, and on the west by the canton of Lucern and the Freye-Amt, or Free

Provinces. It is not above 12 miles either way ; but very populous and fruitful, yielding wine, wheat, chestnuts and other fruits, in its vales, and excellent pasture on its mountains. The inhabitants of this canton are staunch Roman Catholics. It lies in the diocese of Constance, and its government is democratical. There are two lakes in it, abounding in fish, particularly large carps, pikes, and a species of trouts, called *rotels* ; as well as several woods, full of game. Zug, which gives name to it, and is its capital, stands on the east side of a lake of the same name, about seven miles long, and is a strong neat town, containing a priory, and two convents.

ZUINGLIUS (Ulricus), an able and zealous reformer, who laid the foundation of a separation from Rome in Switzerland, at the same time that Luther did the like in Saxony, was born at Wildchausen in 1487. While he officiated as preacher at Zurich, a Franciscan sent by Leo X. came to publish indulgences there ; against which Zuinglius, after the example of Luther, declaimed powerfully. In the course of this opposition he started a new doctrine, which he called *Evangelical Truths* ; and from the beginning of 1519 to 1523, he preached not only against indulgences, but against other articles of the Romish church. But though Zuinglius made no less progress than Luther, he yet conducted himself with more moderation and prudence ; and wishing to have the concurrence of the civil powers, procured two assemblies to be called at Zurich : by the first, he was authorized to proceed as he had begun ; and by the second, the outward worship and ceremonies of the church of Rome were abolished. During these transactions, Zuinglius published several books in defence of his doctrines ; but treating of the eucharist, and prescribing a form of celebrating the Lord's supper, different from Luther, he was involved in violent disputes with the rest of his reforming brethren. The remainder of the Swiss cantons disallowing the proceedings of that of Zurich, other assemblies were called, and things tending to tumult, both sides had recourse to arms ; when Zuinglius, who began as a preacher, died in arms as a soldier, in 1531. His works amount to four vols folio : his doctrines were afterward spread, with some alterations, by Calvin, Beza, and others, whose followers were called *Calvinists*, while the disciples of Zuinglius retained the name of *Sacramentarians*.

ZURICH, a canton of Switzerland, bounded to the north by Swabia and the canton of Schaffhausen ; to the south by the town and territory of Rapperschweil and the cantons of Switz and Zug ; to the east by the Thurgau, Toggenburg, and Uznach ; and to the west by the free bailiages and county of Baden. It is about 60 miles from north to south, and 48 from east to west. With respect to its face, air, and soil, it is said to be an epitome of all Switzerland, as containing in it hills, valleys, plains, corn-lands, vineyards, lakes, and rivers. Their wines have a tartness at first, but the longer they are kept the more agreeable they are. The other products are excellent fruits, corn, pasture, fine clay, chalk, several coloured earthen, pit-coal, turf, and sulphur. There are also some mineral springs in the canton ; and of the lakes, that of Zurich is the most considerable. The reformation was introduced here by Zuinglius, in the year

1517. This canton is the first in rank, and inferior only to that of Bern in extent, power, and wealth; in consequence of which, its representatives preside in the general diets, when held in any place belonging in common to the cantons; and the affairs relating to the whole confederacy are transacted in its offices. Its quota, for the defence of the several members of the confederacy, is 1400 men. Of one of the two armies raised on these occasions, it nominates one of the commanders in chief, as Lucern does the other. Its revenue is said to be about 150,000 crowns a-year; of which, one year with another, two thirds are expended in the charges of government, and the rest laid up in the treasury. It can bring 50,000 fighting men into the field at a very short warning.

ZURICH, the capital of a canton of the same name in Switzerland, stands in a pleasant country, near where the river Aa issues from the lake that takes its name from the town, 23 miles from Schaffhausen, and 114 from Geneva. After having been ruined by Attila, the Hun, it is said to have been restored by Thuricius, son of Theodoric king of the Goths, from whom it took the name of *Thuricum*, corrupted afterwards into that of *Zurich*. The river divides it into two parts, and has two bridges over it. It is fortified in the modern way, and has wide ditches, cast with free stone. There are five arsenals in it, well stored with arms and artillery; an academy or college, having 15 professors; a museum, or chamber of rarities; a stately town-house, the pillars in the front of which are of black marble, streaked with white; and a town library. The sovereignty and administration of all affairs are lodged in the greater and lesser council, out of which are chosen the city-officers, as the councils are out of the 13 companies of burghers. There are several other councils or colleges, each of which has its particular department. Here are a great variety of silk, woollen, linen, cotton, and other manufactures, this being the place of the greatest trade in all Switzerland. Before the reformation, there was an abbey for ladies in this town, whose abbesses had the title of princess; the large revenues of which are now applied mostly to pious and charitable uses. The town is well supplied with provisions by and from its lake. The streets are neat, and houses well-built, but not magnificent. The college here hath produced some learned men, particularly Zuinplius and Bullinger. In the town-library are several letters to Bullinger from lady Jane Gray daughter to the duke of Suffolk. In one of the arsenals is the figure of William Tell, dressed and armed in the ancient Swiss manner, with the cross-bow, whence he shot the arrow that struck the apple off his child's head. The unmarried women here are distinguished from the married, by a particular knot of ribbons on their heads, and the men are generally dressed in black; for the young only are allowed to wear coloured stuffs, and those quite plain, gold, silver, and jewels, being forbid, and luxury and vanity of every

kind carefully guarded against. When they go to church, the men all wear bands, and, when in mourning, bonnets made of pasteboard covered with crape.

Both men and women are so fond of music, that there are few of them that cannot play on some instrument. If a burgher goes out of town, or a peasant enters it, without a sword, they are liable to be fined. No persons, whatever their rank or office may be, are exempted from the sumptuary laws. The burgomasters, who are the same as the advocates at Bern, have the title of excellence. The hospitals here are very neat and well endowed; but they do not affect the ridiculous vanity of lodging the poor in palaces. Not only in this town and canton, and other parts of Switzerland, but also among the Grisons, the ministers all preach covered. The country about the town is very pleasant and fruitful; for both which it is not a little indebted to the lake, that extends 24 miles in length, and about two or three in breadth. The water is of a green colour, supposed to be owing to the melted snow that falls into it from the adjacent mountains. That part of it next Zurich is called the *Lower Lake*, and the other end the *Upper*. The cathedral, or great church here, is collegiate. The present city is said to owe its origin to a nunnery, founded by the emperor Lewis I. near where the ancient Tigurum stood.

ZUTPHEN, a strong and considerable town of the United Provinces, in Guelderland, and capital of a county of the same name. It has a magnificent church, and is surrounded with walls. It was taken by the French in 1672, who in 1674 delivered it up to the States General. It is seated at the confluence of the rivers Berkel and Yessel, nine miles south-east of Deventer, and 55 east by south of Amsterdam.—E. Long. 6. 13. N. Lat. 52. 12.

ZUIDER-ZEE, a great gulph or bay of the German ocean, which extends from south to north in the United Provinces, between Friesland, Over-Yessel, Guelderland, and Holland. It is so called from its situation towards the south, and is said formerly to have been a lake, and that the land is swallowed up which united North-Holland with Friesland.

ZYGOMA, in anatomy, a bone of the head, or rather an union or assemblage of two processes or eminences of bones; the one from the os temporis, the other from the os maxæ: these processes are hence termed the *zygomatic processes*, and the suture that joins them together is denominated the *zygomatic suture*.

ZYGOMATICUS, in anatomy, a muscle of the head, arising from the *Os ZYGOMA*, whence its name, and terminating at the angle of the lips.

ZYGOPHYLLUM, BEAN CAPER; a genus of the monogynia order belonging to the decandria class of plants. There are eight species, partly shrubby and partly herbaceous plants, all natives of warm climates, though some of them are hardy enough to endure the open air in this country.

ACHOR. On the margin, for n° 762, 913. read n° 760, 1009.

ACHRAS, a genus of the monogynia order, belonging to the hexandria class of plants. There are three species; the most remarkable of which are, 1. The sapota, with oblong oval leaves, and smooth turbinate fruit. 2. The mammosa, with spear-shaped

leaves, and large oval fruit. The first is common about Panama, and some places in the Spanish West Indies, but is not to be found in any of the British settlements in America. The second sort is very common in Jamaica, Barbadoes, and most of the West India islands, where the trees are planted in the gardens for their fruit, which is by many persons greatly esteemed. It grows to the height of 35 or 40 feet, having a straight trunk covered with an ash-coloured bark. The branches are produced on every side, forming a regular head; and are beset with leaves near a foot long, and almost three inches broad in the middle. The flowers are a cream colour; and are succeeded by large oval covered by a brownish skin, inclosing a thick pulp of a russet colour, very luscious, and called *natural marmalade*, from its resemblance to that of quinces.—These trees being natives of very hot climates, cannot be preserved in this country except in the warmest stoves.

ACHROMATIC TELESCOPES. For OPTICS, n° 20. read p. 5597.

ACIDS, (*Encycl.*) Acids form one of the general classes into which Salts are usually divided, the other two being called *alkalies* and *neutrals*. The most common and easy method of distinguishing acids is by their peculiar taste; but there are many other properties which equally distinguish them, the principal of which are: 1. With water they combine into a fluid, whose specific gravity is not a medium betwixt the weight of the water and acid separately taken. 2. With spirit of wine they unite into a substance very different from either of the component parts, called *ether*. 3. They unite with absorbent earths, alkalies, animal, metallic, and sometimes with pure argillaceous earths, from which they cannot afterwards be separated without considerable difficulty. 4. They change the blue colour of vegetables to red, and heighten the red colour of those which are so already. 5. If mixed with a fermentable liquor, they will prevent that process from taking place; or if the fermentation has already begun, the acid will put a stop to it. 6. They cannot be frozen but in a degree of cold considerably below

Acid. low 32°, the freezing point of water.

To two of these rules, however, there is an exception; viz. the volatile sulphureous acid, which will neither unite with absorbent earths, nor change the colour of vegetable infusions. But this is not to be attributed to the nature of the acid itself. It arises from the phlogiston with which the volatile sulphureous acid is still combined; for the pure sulphureous acid is not different from that called the *vitriolic*, and is exceedingly strong.

By some philosophers acids have been reckoned simple chemical elements, and by others they have been thought to be formed of water and earth. The former opinion, however, is refuted by some experiments which prove the destructibility of certain acids; and the latter seems not at all probable. We have no instance of an acid being formed out of these two ingredients; nor can we conceive how two substances, seemingly so insipid and inactive, can produce a third with properties so exceedingly different from both. The vegetable acids can all of them be destroyed by means of fire; in which case they yield a great quantity of fixed air, thereby showing that it is properly their element, or that from which they are formed. What are the constituent parts of fixed air, we know not. Dr Priestley supposes it to be a modification of the nitrous acid; but from the great quantities of dephlogisticated air yielded by the latter, this opinion seems also improbable; nor indeed can any thing concerning the origin of fixed air be deduced with certainty from such experiments as have yet been made.

The vitriolic and marine acids are resolved into a kind of air peculiar to themselves; so that we have few or no data to guess at their composition. In their action upon bodies, acids greatly resemble cold, as alkalies do heat; the former always tending to preserve, or even increase, the cohesion of such bodies as they do not chemically dissolve, and consequently to keep them from putrefaction; while alkalis, on the other hand, dissolve the cohesion, and thus sooner bring on the effects of putrefaction.

But although acids thus produce the effects of cold, this is only to be understood of them in a very diluted state; for when concentrated, they are so far from producing cold, that with some bodies a most violent heat, and even flame itself, is engendered. Thus a mixture of the vitriolic and nitrous acid will set on fire oil of turpentine; the nitrous acid alone will kindle oil of cloves, saffron, and some others. In this concentrated state they prove a violent and corrosive poison if taken into the body; though when diluted, they not only may be taken with safety, but in many cases prove medicines of great efficacy; particularly in fevers, where they are useful by their property of allaying thirst, as well as by their tonic and antiseptic qualities.

The acids are divided into three classes expressive of their origin, viz. the mineral, vegetable, and animal. The *mineral* are, the vitriolic, the nitrous, and marine acids; to which we may now add that of arsenic. The *vegetable* are, the acetic acid, that of tartar, the acid juices of fruits, the acids obtained from woods by distillation, and the acid of sugar. The *animal* acids are, that of phosphorus, the acid of ants, wasps, bees, &c.

All or most of the acids, as already mentioned, will unite themselves with alkaline salts, earths, and metals; but some of them have these properties in a much stronger degree than others. The mineral acids particularly excel in this respect; though even among these there are considerable differences. The vitriolic is reckoned the strongest; though it is probably inferior to the acid of arsenic. Of this last, however, the properties are not yet generally known.

The *vitriolic*, or, as it is sometimes called, the *universal acid*, when very pure and strong, appears like a clear oil, having twice the specific gravity of water, or even more; in which state it is called *oil of vitriol*, though improperly, for it has not the least oily quality, but on the contrary mixes with water so violently that a great heat immediately takes place. In this state the smallest quantity of an inflammable substance, such as a bit of cork or straw, falling into it, gives a brownish or black colour; and as this frequently happens to those who sell the acid in small quantities, we very often buy it thus discoloured.

This acid was originally named the *vitriolic*, from its being distilled from vitriol or copperas; and the name is still retained, though this method of distillation is universally superseded by that of obtaining it from the fumes of burning sulphur. It is found almost universally. It exists in vast quantity in sulphur; so that it can be extracted from it with profit even when great part of the acid fumes are lost. In the waters of the ocean it is found combined with calcareous earth, and with the earth called *magnesia*. In the former case, it subsides to the bottom of the salt-pans, forming what is called *pan-gratch*; and in the latter, it produces the bitter purging salt called *Epsom salt*.—In the earth it is found in vast quantities united with calcareous matter, and crystallized in the large masses called *gypsum*, *alabaster*, *Paris plaster*, or *suco*. It is also found in many kinds of hard water united with the same earth, and sometimes with iron; in which case it forms what are called *chalybeate mineral waters*. In clay of all kinds it exists, most frequently combined with calcareous earth, but sometimes with the argillaceous or substance of the clay itself. In this last case the compound formed by the union is *alum*. This acid exists also in great plenty in the pyrites, or hard heavy lumps called *brasses*, found in coal-mines. Here it is combined with inflammable matter, and the compound is *sulphur*; but by exposure to the air the inflammable part flies off, and the acid partly saturates itself with iron, which these substances also contain in plenty, and partly appears in its proper form. Hence the water which washes pyrites thus exposed contains partly a green vitriol formed by the union of the acid with the metal; and partly a loose acid, which if it could be concentrated would become pure oil of vitriol.—Hence probably the origin of vitriolic and acid waters.—It is also frequently found in or near copper mines; and then makes its appearance in a very acrid poisonous water of a bluish colour, from which the blue copperas or vitriol is extracted.

The vitriolic acid is of very considerable use in many different mechanical arts. In tanning of leather, it is used to give consistency to the leather after it has been almost dissolved by the lime. In dyeing, it is of use for fixing and brightening of various colours, especially

Acid.

Acid.

if combined with the argillaceous earth into the compound called *alum*. In bleaching, it is also exceedingly useful for dissolving the impurities which cannot be extracted by fixed alkali, whence the cloth acquires a clearer colour than if no acid was used. In medicine it is a good antiseptic and corroborant. It is useful in many other cases, so that the consumption of it is very great; and though several manufactories of vitriolic acid have been erected, the market cannot be overstocked.

The *nitrous acid*, commonly called *aquafortis*, when pure, is a limpid liquor considerably lighter than oil of vitriol, its weight being to that of water as 19 to 12. A very small quantity of inflammable matter communicates to a large portion of this acid a deep orange or reddish colour, and causes it emit very dense fumes of a red colour and suffocating nature. It is obtained only by distilling the neutral salt called *saltpetre* with oil of vitriol. Concerning its origin there have been great disputes; some asserting that it is naturally contained in the air; others, that it is the effect of putrefaction; some, that it is only the vitriolic acid altered by having been mixed with putrefying vegetable and animal substances; and lastly, which is the most probable opinion, it has been asserted, that the nitrous acid is naturally found in vegetables, and consequently that its being procured in large quantities from putrefied vegetables is not a sign of its being produced, but only exposed to view by that process; and in confirmation of this hypothesis, it is observed, that almost all those salts called *essential* by the chemists, are no other than the nitrous acid combined with volatile alkali. In the earth, this acid is also found in various parts and in many different proportions; but the accounts we have of its production, notwithstanding their being so often repeated by different authors, are still so confused and uncertain, that very little confidence can be put in them.

The uses of *aquafortis* in dyeing, and in other mechanic arts, is very considerable. It affords one method of separating gold from silver, being endowed with a power of dissolving the latter, but not the former. It is also of considerable use in chemistry and medicine, particularly in the making of gun-powder; for to this we must ascribe the whole power exerted by the explosion of that composition. In this case, however, it is not made use of in its pure state, but in conjunction with a fixed alkali, forming the neutral salt called *nitre* or *saltpetre*.

Though the nitrous acid is weaker than the vitriolic, in point of chemical affinity and quantity of acid power, yet it acts much more briskly upon all substances than the former; and by its means the vitriolic acid may be made to dissolve many which it cannot do by itself. Being used for so many purposes, the consumption of nitre is immense.

The *marine acid*, muriatic acid, or acid of sea-salt, has its name from being found in the waters of the ocean, forming our common salt in conjunction with the fossil fixed alkali. Besides this, and the fossil or rock-salt, which is of the same nature with the salt of the ocean, the marine-acid has no other origin excepting the bitter liquor which remains after the extraction of sea-salt. Here it is found in combination with the earth called *magnesia*, forms a liquor very pun-

gent to the taste, which cannot be crystallized; and if evaporated to dryness, soon attracts moisture from the air sufficient to reduce it again to a fluid state.

The marine acid is the weakest and the lightest of all the mineral acids. In its most concentrated state it is of a lemon-colour, continually exhaling dense white fumes which spread to a great distance, and are of a very suffocating nature. The marine acid is scarce ever concentrated equally with the other two, on account of its being much more volatile; and therefore its specific gravity cannot well be ascertained. The marine acid dissolves metals with less heat and ebullition, and fewer vapours, than the other two, but adheres to them with much more obstinacy; so that almost all the metals, even gold itself, become volatile, and arise with this acid in form of a sublimate. The uses of marine acid, except what is employed in sea-salt, are very limited, and therefore there is no great demand for it. However, it is useful in the solution of some metals, particularly gold; in which case it is mixed with a proportion of *aquafortis*, and then forms a compound called *aqua regia*.

The *VEGETABLE* acids most generally used are *vinegar* or the *acetous acid*, and the *acid of tartar*. The former is produced by a kind of fermentation; the latter from wine which is long kept, and seems to be a kind of essential salt. The uses of vinegar as an article of food are very extensive. It is also the basis of some elegant and useful medicines. Cream of tartar makes no inconsiderable article in the materia medica, and is also used in some of the mechanic arts. The other vegetable acids are but little known or made use of, the acid juices of fruits excepted, which are almost entirely confined to culinary purposes.

With regard to the *ANIMAL* acids, that of phosphorus excepted, they have been very little the subject of investigation. The phosphoric acid, however, is not entirely confined to the animal kingdom. It is obtained by distillation from mustard, and some other vegetables. By means of the vitriolic acid also, it may be had in great quantity from calcined bones and other animal earths. The only substance from which it can be had without the trouble of distillation, is urine.—By simple evaporation, a kind of salt composed of phosphoric acid and volatile alkali is obtained. The phosphoric acid being used only for matters of curiosity, the consumption of it is inconsiderable.

ACIDUM PINGUE, an imaginary acid, which some German chemists supposed to be contained in fire, and by combining with alkalies, lime, &c. to give them their caustic properties; an effect which is found certainly to depend on the loss of their fixed air. ADMIRALTY ISLANDS, lie in about 2° 18' S. Lat and 146° 44' E. Long. There are between twenty and thirty islands said to be scattered about here, one of which alone would make a large kingdom. Captain Carteret, who first discovered them, was prevented touching at them, although their appearance was very inviting, on account of the condition of his ship, and of his being entirely unprovided with the articles of barter which suit an Indian trade. He describes them as clothed with a beautiful verdure of woods, lofty and luxuriant, interspersed with spots that have been cleared for plantations, groves of coconut trees, and houses of the natives, who seem to be very numerous. The largest of these islands is eighteen leagues long in the direction of east and west. The discoverer thinks it highly probable that these islands produce several valuable articles of trade, particularly spices, as they lie in the same climate and latitude as the Moluccas.

AIR, (*Encycl.*) The general mass of fluid which goes by the name of air, however simple and homogeneous it may have been thought in former times, is so far from possessing the simplicity of an element, that it is the receptacle of all kinds of effluvia produced from terrestrial substances either naturally or artificially. Hence, whatever may be the nature of the aerial fluid when absolutely pure, that which we breathe, and commonly goes under the name of *air*, must be considered as an exceedingly heterogeneous mixture, various at various

times, and which it is by no means possible to analyse with accuracy.

Though, in this view, air seems to be a kind of sink or common sewer, where all the poisonous effluvia arising from putrid and corrupted matters are deposited; yet it has a wonderful facility of purifying itself, and one way or other of depositing these vapours contained in it; so that it never becomes noxious except in particular places, and for a short time, the general mass remaining upon all occasions pretty much the same. The way in which this purification is effected is different, according to the nature of the vapour with which the air is loaded. That which most universally prevails is water; and from experiments it appears, that the quantity of aqueous vapour contained in the atmosphere is immense. Dr Halley, from an experiment on the evaporation from a fluid surface heated to the same degree with that given by our meridian sun, has calculated, that the evaporation from the Mediterranean sea alone is sufficient to yield all the water of the rivers which run into it. Dr Watson, in his *Chemical Essays*, has given an account of some experiments made with a view to determine the quantity of the water raised from the earth itself in time of drought; and calculates, that, when there had been no rain for above a month, and the grass was become quite brown and parched, the evaporation from an acre was not less than 1600 gallons in 24 hours. Making afterwards two experiments, when the ground had been wetted by a thunder-shower the day before, the one gave 1973, the other 1905, gallons in 12 hours. From this the air is every moment purified by the ascent of the vapour, which continually flies off into the clouds, thus leaving room for the exhalation of fresh quantities; so that as the vapour is considerably lighter than the common atmosphere, and of consequence ascends with great velocity, the air during all this time is said to be *dry*, notwithstanding the vast quantity of aqueous fluid that passes through it.

Nor is it only from the aqueous vapour that the air is purified at this time. Much of that vapour arising from decayed and putrid animal and vegetable substances, and which by modern philosophers is called *phlogiston*, attaches itself to the aqueous vapour, and ascends along with it. Another part is absorbed by vegetables; for the phlogistic vapour, as has been shown under *AGRICULTURE*, n° 5. is probably the food of plants. The phlogistic vapours which ascend along with the aqueous ones, probably continue there and descend along with the rain; whence the fertilizing qualities of rain-water above those of any other. Thus we may see why a dry air, whether cold or hot, must always be wholesome; but as the atmosphere cannot always receive vapours, it is obvious, that when great rains come on, especially if attended with heat, the lower regions of the air must be overloaded with vapours both of the aqueous and phlogistic kind, and of consequence be very unwholesome.

But besides the aqueous and phlogistic vapours, both of which are specifically lighter than common air, there are others, which, being specifically heavier, cannot be carried off in this manner. Hence these gross vapours contaminate certain places of the atmosphere, rendering them not only unhealthy, but absolutely poisonous. Of these are, 1. Sulphureous, acid, capillary,

Air. and metalline exhalations. These are produced principally by volcanoes; and as they descend in consequence of their specific gravity, they suffocate and spread destruction all around them, poisoning not only animals, but vegetables also. 2. The vapours arising from houses where lead and other metals are smelted, have the same pernicious qualities; inasmuch that the men who breathe them, the cattle who eat the grass, and the fishes who inhabit the waters on which they fall, are poisoned by them if taken into the body in a certain proportion. 3. Of the same kind are the *mofcets*, or emanations of fixed air which sometimes proceed from old lavas, or perhaps from some other places even of the surface. From all these the air seems not capable of purifying itself, otherwise than either by dispersing them by winds, or by letting them subside by their superior gravity, till they are absorbed either by the earth or water, according as it is their nature to unite with one or other of these elements. 4. Of this kind also seem to be those vapours which are called properly *pestifential*. The contagion of the plague itself seems to be of an heavy sluggish nature, incapable of arising in the air †, but attaching itself to the walls of houses, bed-cloaths, and wearing apparel. Hence scarce any constitution of the atmosphere can dispel these noxious effluvia; nor does it seem probable that pestifential distempers ever cease until the contagion has operated so long, and been so frequently communicated from one to another, that, like a ferment much exposed to the atmosphere, it becomes vapid, communicates a milder infection, and at last loses its strength altogether.

† See *Medicines*,
no 149.

Mechanical Properties of the Air.—In common with water, the air we breathe possesses *gravity*, and consequently will perform every thing which water can do, making allowance for the great difference between the specific gravity of water and of air. This difference indeed is exceedingly great, and has been variously calculated. Ricciolus estimates the gravity of air to be to that of water as 1 to 1000; Merfennus, as 1 to 1300, or 1 to 1356; Lana, as 1 to 640; and Galileo, only as 1 to 400. But Mr Boyle, by more accurate experiments, makes the air at London to be to water as 1 to 938; and thinks, that, all things considered, the proportion of 1 to 1000 may be taken as a medium. But by three experiments made since that time before the Royal Society, the specific gravity of the air was determined to be to that of water as 1 to 840, 852, and 860. By a very accurate experiment, Mr Hauksbee fixed the proportion as 1 to 885. But as all these experiments were made when the barometer was at 29½ inches, Dr Jurin supposes, that, at a medium between heat and cold, when the barometer is 30 inches high, the proportion between the two fluids may be taken as 1 to 800; and this agrees with the observations of the Hon. Mr Cavendish, made when the barometer was at 29½ inches, and the thermometer at 50.

By means of its gravity, the air presses with great force upon all bodies, according to the extent of their surface. M. Pascal has computed the quantity of this pressure to be no less than 2322 pounds upon every square foot of surface, or upwards of 15 pounds on every square inch. According to some experiments made by M. Amontons and de la Hire, a column of

air on the surface of the earth, and 36 fathoms high, is equal in length to three lines depth of mercury. From the barometer, however, we know that the whole pressure of the atmosphere is very different; sometimes being equal only to a column of 28 inches, and varying from thence to 31 inches. The whole quantity of pressure must thus be immense, and has been computed equal to a globe of lead 60 miles in diameter.

By means of its gravity, the atmosphere accomplishes many useful purposes in nature. It prevents the arterial vessels of animals and the sap-vessels of plants from being too much distended by the expansive power (whatever it is), which has a perpetual tendency to swell them out. Thus we see, that, in the operation of cupping, where the pressure of the air is taken off from a particular part, the expansive force instantly acts, and swells out the vessels to a great degree. Hence also, when animals are put into an air-pump, their whole bodies swell.

By its gravity also, the air promotes the union of fluid bodies, which would instantly cease in *vacuo*. Thus oils and salts, which remain united in air, separate as soon as that fluid is extracted. Hence also, when hot water is put under an exhausted receiver, it boils violently; because, the pressure of the air being now taken off, the particles of steam, which existed invisibly among the water, and which the gravity of the atmosphere prevented from flying off so soon, are now hurried up with great velocity, by means of the excessive comparative gravity of the aqueous fluid.

On the gravity of the air depend the ascent of water in pumps, syphons, &c. and likewise all the phenomena of the barometer.

Besides its gravity, which the air has in common with water and other fluids, there is another, which it has only in common with steam or vapour. This is called its *elasticity*; by which, like a spring, it allows itself to be compressed into a smaller bulk, and then returns again to its original size upon removing the pressure.

This property of the air was first ascertained by some experiments of lord Bacon, who, upon this principle, constructed his *vitrum calendare*, the first thermometer. Of this power we have numerous proofs. Thus, a blown bladder being squeezed in the hand, we find the included air sensibly resist; so that, upon ceasing to compress, the cavities or impressions made in its surface are readily expanded again and filled up.

On this property of elasticity the structure and office of the *Air-Pump* depend. Every particle of air always exerts this nius or endeavour to expand, and thus strives against an equal endeavour of the ambient particles; whose resistance happening by any means to be weakened, it immediately diffuses into an immense extent. Hence it is that thin glass bubbles, or bladders filled with air, and exactly closed, being included in the exhausted receiver of an air-pump, burst by the force of the included air. So a bladder quite flaccid, containing only the smallest quantity of air, swells in the receiver and appears quite full. The same effect is also found, by carrying the flaccid bladder to the top of an high mountain.

It has been questioned among philosophers, whether this elastic power of the air is capable of being destroyed or diminished. Mr Boyle made several experiments

with a view to discover, how long air brought to the greatst degree of expansion to which he could reduce it in his air-pump, would retain its spring; and could never observe any sensible diminution. Desaguliers found, that air, after having been inclosed for half a year in a wind-gun, had lost none of its elasticity; and Roberval, after preserving it in the same manner for 16 years, observed, that its expansive projectile force was the same as if it had been recently condensed. Nevertheless, Mr Hauksbee concludes, from a latter experiment, that the spring of the air may be so disturbed by a violent pressure, as to require some time to return to its natural tone. Dr Hales inferred, from a number of experiments, that the elasticity of the air is capable of being impaired and diminished by a variety of causes.

The weight or pressure of the air, it is obvious, has no dependence on its elasticity; but would be the same whether the air had such a property or not. But the air, being elastic, is necessarily affected by the pressure, which reduces it into such a space, as that the elasticity, which re-acts against the compressing weight, is equal to that weight. In effect, the law of this elasticity is, that it increases as the density of the air increases; and the density increases as the force increases by which it is pressed. Now there must necessarily be a balance between the action and re-action; i. e. the gravity of the air which tends to compress it, and the elasticity of the air which endeavours to expand it, must be equal. Hence the elasticity increasing, or diminishing universally, as the density increases or diminishes, i. e. as the distance between the particles diminishes or increases, it is no matter whether the air be compressed and retained in such space by the weight of the atmosphere, or by any other means; it must endeavour in either case to expand with the same force. And as hence, if air near the earth be pent up in a vessel, so as to cut off all communication with the external air, the pressure of the inclosed air will be equal to the weight of the atmosphere. Accordingly, we find mercury sustained to the same height, by the elastic force of air inclosed in a glass vessel, as by the whole atmospheric pressure. On the same principle air may be artificially condensed; and hence the structure of the *Air-Gun*.

The utmost limits to which air of the density which it possesses at the surface of the earth, is capable of being compressed, have not been ascertained. Mr Boyle made it 13 times more dense; Dr Halley says that he has seen it compressed so as to be 60 times denser than in its natural state, which is farther confirmed by M. Papin, and M. Høuygens. Dr Hales, by means of a press, condensed it 38 times; and by forcing water in an iron ball or globe, into 1551 times less space than it naturally occupies. However, Dr Halley has asserted, in the *Philosophical Transactions*, Abr. vol. ii. p. 17, that from the experiments made at London, and by the academy del Cimento at Florence, it might be safely concluded, that no force whatever is able to reduce air into 800 times less space than that which it naturally possesses on the surface of our earth. In answer to which, M. Amontons, in the *Memoirs of the French Academy*, maintains, that there is no fixing any bounds to its condensation; that greater and greater weights will still reduce it into less and less compass;

that it is only elastic in virtue of the fire which it contains; and that as it is impossible ever absolutely to drive all the fire out of it, it is impossible ever to make the utmost condensation.

The dilatation of the air, by virtue of its elastic force, is found to be very surprising; and yet Dr Wallis suggests, that we are far from knowing the utmost of which it is capable. In several experiments made by Mr Boyle, it dilated first into 9 times its former space; then into 31 times; then into 60; then into 150. Afterwards it was brought to dilate into 8000 times its space, then into 10000, and even at last into 13679 times its space; and this altogether by its own expansive force, without the help of fire. On this depends the structure and use of the *MANOMETER*.

Hence, it appears, that the air we breathe near the surface of the earth, is compressed by its own weight into at least the 13679th part of the space it would possess *in vacuo*. But if the same air be condensed by art, the space it will take up when most dilated, to that it possesses when condensed, will be, according to the same author's experiments, as 550000 to 1.

M. Amontons, and others, we have already observed, attribute the rarefaction of the air wholly to the fire contained in it; and therefore, by increasing the degree of heat, the degree of rarefaction may be carried still farther than its spontaneous dilatation. Air is expanded one-third of its bulk by boiling water.

Dr Hales found, that the air in a retort, when the bottom of the vessel was just beginning to be red-hot, was expanded through twice its former space; and in a white, or almost melting heat, it occupied thrice its former space; but Mr Robins found, that air was expanded by the heat of iron, just beginning to be white, to four times its former bulk. On this principle depends the structure and office of the *THERMOMETER*.

M. Amontons first discovered that air will expand in proportion to its density, with the same degree of heat. On this foundation the ingenious author has a discourse, to prove "that the spring and weight of the air, with a moderate degree of warmth, may enable it to produce even earthquakes, and other of the most vehement commotions of nature."

According to the experiments of this author, and M. de la Hire, a column of air on the surface of the earth 36 fathoms high, is equal in weight to three lines depth of mercury; and it is found, that equal quantities of air possess spaces reciprocally proportional to the weights with which they are pressed: the weight of the air, therefore, which would fill the whole space possessed by the terrestrial globe, would be equal to a cylinder of mercury, whose base is equal to the surface of the earth, and its height containing as many times three lines as the atmospherical space contains orbs equal in weight to 36 fathoms of that wherein the experiment was made.—Hence, taking the denseness of all bodies, *e. g.* gold, whose gravity is about 14630 times greater than that of air in our orb, it is easy to compute that this air would be reduced to the same density as gold, by the pressure of a column of mercury 14630 times 28 inches high, i. e. 409640 inches: since the bulks of air in that case would be in the reciprocal ratio of the weights by which they are pressed. These 409640 inches, therefore, express the height at which the barometer must stand, where the

Air.

Air.

air would be as heavy as gold, and the number ²¹⁶³¹₂₀₅₆₀ lines, the thickness to which our column of 36 fathoms of air would be reduced in the same place. Now, we know that 43528 fathoms, which is the depth where the above pressure and consequent reduction take place, are only the 74th part of the semi-diameter of the earth; and therefore, beyond that depth, whatever matter exists, it must be heavier than gold. It is not improbable, therefore, that the remaining sphere of 645538 fathoms diameter may be full of dense air, heavier by many degrees than the heaviest bodies which we know. Hence again, as it is proved, the more air is compressed, the more does the same degree of fire increase the force of its spring, and render it capable of a proportionably greater effect; we may infer, that a degree of heat, which in our orb can only produce a moderate effect, may have a very violent one in such lower orb; and that, as there may be many degrees of heat in nature beyond that of boiling-water, it is probable there may be some whose violence thus assisted by the weight of the air, may be sufficient to tear asunder the solid globe. See the article EARTHQUAKE.

The elastic power of the air is the second great source of the effects of this important fluid. By means of this it insinuates into the pores of bodies possessing this prodigious faculty of expanding, which is so easily excited that it must necessarily put the particles of bodies into which it insinuates itself into perpetual oscillations. Indeed, the degree of heat, and the air's gravity and density, and consequently its elasticity and expansion, never remaining the same for the least space of time, there must be an incessant vibration or dilatation and contraction in all bodies.

We observe this reciprocation in several instances, particularly in plants, the trachea or air-vessels of which do the office of lungs; for the contained air alternately expanding and contracting, as the heat increases or diminishes, by turns presses the vessels and eases them again, and thus promotes a circulation of their juices.

Hence we find, that no vegetation or germination will proceed *in vacuo*. Indeed, beans have been observed to grow a little tumid therein; and this has led some to attribute that to vegetation which was really owing to no other cause than the dilatation of the air within them. The air is very instrumental in the production and growth of vegetables, not only by invigorating their several juices while in an elastic active state, but also by greatly contributing in a fixed state to the union and firm connection of their several constituent parts.

From the same cause it is, that the air contained in bubbles of ice, by its continual action, bursts the ice; and thus glasses and other vessels frequently crack when their contained liquors are frozen. Thus also, entire columns of marble sometimes cleave in the winter time, from some little bubble of included air's acquiring an increased elasticity. From the same principle arise all putrefaction and fermentation; neither of which will proceed, even in the best disposed subjects, *in vacuo*.

Since we find such great quantities of elastic air generated in the solution of animal and vegetable substances, a good deal must constantly arise from the

dissolution of these elements in the stomach and bowels, which is much promoted by it.

In reality, all natural corruption and alteration seem to depend on air; and metals, particularly gold, only seem to be durable and incorruptible, in virtue of their not being pervious to air.

Air, effects of the different ingredients of it.—Air not only acts by its common properties of gravity and elasticity, but there are numerous other effects arising from the peculiar ingredients of which it consists.

Thus, 1. It not only dissolves and attenuates bodies by its pressure and attrition, but as a chaos containing all kinds of menstua, and consequently possessing powers for dissolving all bodies. It is known that iron and copper readily dissolve and become rusty in air, unless well defended with oil. Boerhaave assures us, that he has seen pillars of iron so reduced by air, that they might be crumbled to dust between the fingers; and as for copper, it is converted by the air into a substance much like the verdigrise produced by vinegar.

Mr Boyle relates, that in the southern English colonies the great guns rust so fast, that after lying in the air for a few years, large cakes of crocus martis may be separated from them. Acosta adds, that in Peru the air dissolves lead, and considerably increases its weight. Yet gold is generally esteemed indissoluble by air, being never found to contract rust, though exposed to it ever so long. The reason may be, that sea-salt, which is the only menstruum capable of acting on gold, being very difficult to volatilize, there is but a small proportion of it in the atmosphere. In the laboratories of chemists, where aqua regia is prepared, the air becoming impregnated with an unusual quantity of this salt, gold contracts a rust like other bodies.

Stones also undergo the changes incident to metals. Thus Purbeck stone, of which Salisbury cathedral consists, is observed gradually to become softer, and to moulder away in the air; and Mr Boyle gives the same account of Blackington stone. He adds, that air may have a considerable operation on vitriol, even when a strong fire could act no farther upon it. And he has found, that the fumes of a corrosive liquor work more suddenly and manifestly on a certain metal when sustained in the air, than the menstruum itself did, which emitted fumes on those parts of the metal which it covered; referring to the effects of the effluvia of vinegar on copper.

The dissolving power of air is increased by heat, and by other causes. It combines with water; and by access of cold, deposits part of the matter which was kept dissolved in it by a greater degree of heat. Hence, the water, by being deposited and condensed upon any cold body, such as glass, &c. in windows, forms fog, and becomes visible. Air, likewise, by means of its dissolving power, accelerates evaporation and distillation.

2. Air volatilizes fixed bodies. Thus, sea-salt being first calcined, then fused by the fire, and when fused exposed to the air to liquefy; when liquified set to dry, and then fused again, repeating the operation; will by degrees be almost wholly evaporated, nothing but a little earth remaining. Helmont mentions it as an arcanum in chemistry, to render fixed salt of tartar volatile; but this is easily effected by air alone; for

if some of this salt be exposed to the air, in a place replete with acid vapours, the salt draws the acid to itself, and, when saturated with it, is volatile.

3. Air also fixes-volatile bodies. Thus, though spirit of nitre or aquafortis readily evaporate by the fire, yet if there be any putrefied urine near the place, the volatile spirit will be fixed, and fall down in form of aqua secunda.

4. Air brings many quiescent bodies into action; i. e. excites their latent powers. Thus, if an acid vapour be diffused through the air, all the bodies of which that is the proper menstrum, being dissolved by it, are brought into a state proper for action.

In the various operations of chemistry, air is a very necessary and important agent; the result of particular processes depending on its presence or absence, on its being open or inclosed. Thus, the parts of animals and vegetables can only be calcined in open air; in close vessels they never become any other than black coals. And these operations are affected by the changes to which the air is liable. Many instances might be adduced to this purpose. Let it suffice to observe, that it is very difficult to procure oil of sulphur, *per campum*, in a clear dry atmosphere; but in a thick moist air it may be obtained with greater ease, and in larger quantities. So pure well-fermented wine, if it be carried to a place where the air is replenished with the fumes of new wine then fermenting, will begin to ferment afresh.

The changes in the air arise from various causes, and are observable, not only in its mechanical properties, such as gravity, density, &c. but in the ingredients that compose it. Thus, at Fahlun in Sweden, noted for copper-mines, the mineral exhalations affect the air in such a manner as to discolour the silver coin in purses; and the same effluvia change the colour of brass. In Carniola, Campania, &c. where are mines of sulphur, the air sometimes becomes very unwholesome, which occasions frequent epidemic diseases, &c.

The effluvia of animals also have their effect in varying the air; as is evident in contagious diseases, plagues, murrains, and other mortalities, which are spread by an infected air.

For the vivifying principle of air, see the article *Blood*, (*En cycl.*)

Different kinds of Air. The late numerous discoveries and improvements relating to this subject have not been more interesting to philosophers, than useful to science and beneficial to society. Many perplexing processes in chemistry have been explained in consequence of those discoveries, several have been facilitated, and a number of new and useful ones have been introduced. The phenomena attending metallic calcinations and reductions have been greatly elucidated. The knowledge of the use of the air in respiration; the method of ascertaining its purity, and fitness for that function; the investigation of deplogified air; the method of impregnating water with fixed air; are all calculated to answer purposes of the highest utility. The medicinal properties of fixed air have been in a great measure ascertained, and its antiseptic qualities in other respects promise to be of considerable advantage. The method of ascertaining the purity of the air of a place, and the manner of ventilating an apartment, are of great use for those concerned in public

buildings. In short, there is perhaps no station in life where some knowledge of this subject may not be of use. Although, therefore, the different kinds of air have already been treated of at some length in various parts of this work, yet to render a subject so useful in itself, and so frequently agitated in conversation, more generally intelligible, a short recapitulation, with necessary additions, shall here be given.

1. *Fixed or Fixable Air*, or *Aerial Acid*, is perhaps the oldest permanently elastic fluid different from common air that has been known to mankind. Its pernicious qualities of suffocating animals and extinguishing flame indeed, are those by which it chiefly, if not entirely manifested itself for a long time, nor have its good properties been discovered till very lately. By the miners, who too frequently feel the fatal effects of it, this kind of air is called the *choke-damp*. It is found, however, not only in mines, but in various caverns, wells, and cellars, or other places which have not been ventilated for a long time; and it is also found in various mineral waters from whence it is continually escaping; so that at these springs there is generally a superincumbent body of fixed air of a considerable depth. It has often happened, that people who for the sake of heat having gone to sleep near brick-kilns, have been found dead; owing, no doubt, to the fixed air and other noxious vapours exhaling from the bricks during the time of burning. The grotto del Cani in Italy has long been famous for the stratum of fixed air which lies at the bottom of it, which suffocates small animals whose heads cannot reach above it, or even the largest if their heads are held down in it for a very short time. In some places where this kind of air is naturally produced, its generation continues only for a time, and then ceases. In others it is continual; but, in general, in all places where this air is found naturally, it is mixed with a considerable quantity of common air. Hence it sometimes extinguishes flame, where it is not fatal to animals; and frequently some other fluids, as inflammable and phlogificated air are mixed with it.

Fixed air is artificially produced in three different ways; viz. by fermentation, by heat, and by acids. When vegetable or animal-substances, especially the former, are fermented, they yield a great quantity of fixed air. In breweries, on the surface of the fermenting liquor, there is always a stratum of fixed air reaching as high as the edge of the vats; so that if these vessels are deep, and the fermenting liquor much below their edges, the above-mentioned stratum may be some feet in thickness. The same phenomenon is observable in the fermentation of wines in general; and it is owing to the production and elasticity of fixed air, that fermenting liquors, when put into close vessels, often burst them with great violence. The case is the same whatever substance it is that undergoes the vinous fermentation, though the quantity of fixed air produced is not the same in all substances, nor even in the same substance at different times. From 42 cubic inches of beer, Dr Hales obtained 639 cubic inches of air in 13 days. From a quantity of sugar undergoing the vinous fermentation, Mr Cavendish obtained 50 much fixed air, that out of 100 parts of the former, 57 appeared to have been volatilized and converted into fixed air.

But though a vast quantity of fixed air escapes du-

Air. ring this process of fermentation, a very considerable portion still remains united with the fermented liquor, and to this it owes all its brilliancy, and agreeable pungent acidulous taste; for when the fixed air is totally evaporated, the liquor becomes entirely vapid and flat. Hence also we are furnished with a method of restoring the brilliancy to these liquors after they have lost it in consequence of being exposed to the atmosphere, viz. by impregnating them again with fixed air, either naturally or artificially produced.

Dr Priestley has made several experiments in order to determine the quantity of fixed air contained in several sorts of wine. His method was to take a glass vial (fitted with a ground stopple and tube), capable of containing 1½ ounce measure. This he filled with wine, plunging it into a proper vessel of water. The whole was then put over the fire, and the water, into which the phial was plunged, suffered to boil. The end of the tube being placed under the mouth of an inverted receiver filled with quicksilver, the heat expelled the fixed air from the wine, which entering into the receiver ascended in bubbles through the quicksilver to the top, pushing out part of the metal and taking its place. The result of his experiments was as follows.

| | | | |
|-------------------------|---------------------------|--------------------------------|------------------------------|
| 1½ oz. measure of | Madeira | contained of pure fixed air | } of an ounce measure. |
| | Port of six years old | | |
| | Hock of five years | | |
| | Barrelled claret | | |
| | Tokay of 16 years | | |
| | Champagne of two years | | |
| | Bottled cyder of 12 years | 2 oz. measures. | |
| | | 3½ ditto. | |

During the acetous fermentation also, liquors emit a vapour, great part of which is fixed air, though the nature of its other component parts has not yet been thoroughly ascertained.

Fixed air is likewise produced, though in no great quantity, by putrefaction. In this case, however, a great part of the elastic fluid consists of inflammable and phlogisticated air, and the fixed air itself seems to be intimately connected with a putrid offensive effluvia. "It seems (says Dr Priestley) to depend in some measure upon the time and other circumstances in the dissolution of animal or vegetable substances, whether they yield the proper putrid effluvia, or fixed, or inflammable air."

The elastic fluid produced by putrefying vegetables, when kept in a moderate degree of heat, is almost all fixed air; while that from animal substances contains several times more inflammable than fixed air. Vegetable substances yield almost all the permanently elastic fluid in a few days, but animal bodies continue to emit it for several weeks. When the elastic fluid yielded by animal substances is absorbed by water, and that water boiled, the fixed air may then be obtained without any mixture of the putrid effluvia. It is also to be observed, that the quantity of elastic fluid producible from animal substances is various according to the nature of the parts of the animal employed. Thus, the muscular parts will yield less elastic fluid, and also less mixed with any putrid or offensive effluvia, than a whole animal, or than the liver, &c. The proportion of inflammable and of fixed air is also various, according to the various parts employed.

In every combustion, except that of sulphur or of

metals, a quantity of fixed air is generated. This may be observed by fixing a lighted candle in an inverted receiver over a basin of lime water, for a precipitation of the lime will presently ensue; and the same precipitation (which is one of the characteristics of fixed air) will always ensue, whether a candle, a burning piece of wood, or, in short, any other combustible substance, except sulphur or metals, be made use of.

During this production or extrication of fixed from atmospheric air, the latter is always considerably diminished. If a piece of charcoal be burned by throwing the focus of a lens upon it when contained in a glass receiver inverted in water, after the apparatus is cooled, the water will have mounted a small way into the receiver. The diminution, however, is limited, and depends on several circumstances. Dr Hales has observed, that, in equal receivers, the air suffers a greater diminution by burning large candles than small ones; and likewise that, when equal candles are made use of, the diminution is greater in small than in large receivers. The cause of this phenomenon probably is, that the air contained in the receiver cannot all come into contact with the flame of the candle; whence, as soon as the air which is nearest the flame becomes contaminated, the candle is extinguished. Thus the author of a Concise Treatise on the Various Kinds of Permanently Elastic Fluids, has diminished the air of an inverted receiver one sixth part, by moving the candle whilst it burned through the different parts of the vessel, so that the flame was brought into contact with a greater quantity of the confined air than if it had remained in one situation till it became extinct. Dr Mayow observed, that by the burning of a candle the air was diminished of one thirtieth only; Dr Hales found it to be diminished of one twenty-sixth part; and Dr Priestley found it to be diminished of one fifteenth or sixteenth. Mr Cavendish observed, that air suffered a diminution of one-tenth of the whole quantity, by passing through an iron-tube filled with red-hot powder of charcoal. A candle, or any other combustible body, will cease to burn by itself, and consequently to contaminate a quantity of confined air much sooner, than when it is, in some manner, forced to burn by the external application of heat. "The focus of a burning mirror," says Dr Priestley, "thrown for a sufficient time either upon brimstone or wood, after it has ceased to burn of its own accord, and has become charcoal, will have a much greater effect of the same kind, diminishing the air to its utmost extent, and making it thoroughly noxious." The combustion of the phosphorus of urine diminishes air in a great degree. Mr Lavoisier has observed, that by the combustion of phosphorus, air may be diminished of about one-fifth or one-sixth. This accurate philosopher has also observed, that the acid of phosphorus thus formed, acquires the weight lost by the diminished air; finding that about three inches of air were absorbed by every one grain of phosphorus, when the experiment was tried with a receiver inverted in water, upon the surface of which a small quantity of oil had been introduced; but when the receiver was inverted in quicksilver, the absorption was constantly between two one-fourth and two three-fourth inches for each grain. Mr Cavallo mentions his having often repeated the experiment of burning phosphorus in a glass tube inverted in

Air.

in water, by applying the closed part of the tube wherein the phosphorus was contained, to a pretty strong fire, when he always observed that the utmost diminution of the inclosed air effected by this means was full one-fifth.

Dr Hales remarked, that after the extinction of candles in a receiver, the air continued to diminish for several days after. This may be owing to the gradual absorption of part of it by the water; it having been remarked by Dr Priestley, "that this diminution of air by burning is not always immediately apparent, till the air has passed several times thro' water; and that when the experiment was made with vessels standing in silver instead of water, the diminution was generally inconsiderable till the air had passed through water."

In these experiments of burning combustible bodies in a quantity of air, and measuring the diminution, we should always remark two causes of mistake, viz. the absorption of air by the coaly residuum of the burned matter, which sometimes is very considerable, or by the fluid in which the receiver is inverted, and the production of elastic fluid from the burning substances; thus gunpowder generates a great quantity of elastic fluid when inflamed, &c.

Even the electric spark separates fixed air from common atmospheric air; for when a number of these sparks are taken in a small quantity of common air over lime-water, a diminution will take place, the lime will be precipitated, and if we put a blue vegetable juice instead of the lime-water, it will be turned red by the acidity of the fixed air deposited upon it. Dr Priestley having cemented a wire into one end of a glass tube, the diameter of which was about one tenth of an inch, and having fixed a brass ball to that extremity of the wire which was out of the tube, filled the lower part of it with the juice of turnsole or archil, so that a quantity of common air was contained in the tube between the extremity of the wire and the surface of the liquor. Then taking electric sparks between the said wire and liquor for about one minute, the upper part of the liquor began to look red, and in about two minutes it was manifestly so. The air, at the same time, was diminished in proportion as the liquor became red; but when the diminution arrived to be one-fifth of the quantity of the air contained, then a longer electrization produced no sensible effect. "To determine," says the doctor, "whether the cause of the change of colour was in the air or in the electric matter, I expanded the air which had been diminished in the tube by means of an air-pump, till it expelled all the liquor, and admitted fresh blue liquor in its place; but after that, electricity produced no sensible effect, either on the air or on the liquor; so that it was evident that the electric matter had decomposed the air, and had made it deposit something that was of an acid nature."

The calcination of metals, as we have already observed, phlogisticates, and consequently diminishes common air; but does not produce any fixed air, since the lime-water, over which the calcination is made, does not become turbid; and when metallic calxes are exposed to a sufficient strong heat, they in general yield some fixed air: so that it seems that the fixed air which is formed in the act of the calcination of metals is absorbed by the calx. Some fixed air may be obtained from red lead, by no greater degree of heat than that

of the flame of a candle applied to the phial that contains it.

Easy methods of obtaining Fixable Air for occasional Experiments, &c.

1. *By Fermentation.* Mix together equal parts of brown sugar and good yeast of beer, to which add about twice the bulk of water. This mixture being put into a phial, to which a bent tube with a cork may be adapted, will yield a considerable quantity of fixed air, which may be received into a vial filled with quick-silver or water, as in the following process.

2. *By Acids.* Let a glass tube, open at both ends, be bent, by means of a blow-pipe and the flame of a candle, nearly into the shape of an S, as it is represented by AB, and fix a cork D to one of its extremities, so as to fit the neck of a common vial, that may hold about four or five ounces measure. The hole through the cork may be made with an iron wire red-hot, and the tube may be fastened in it with a bit of soft wax, so as not to let any air go through. Fill a similar vial, or any glass receiver K, with water, and invert it after the manner shown above, in a basin HI, about half filled with water. Now put some chalk or marble, grossly powdered, into the bottle E, so as to fill about a fourth or fifth part of it, and upon it pour some water, just enough to cover the chalk; then add some oil of vitriol to it, which needs not be more than about the fourth or fifth part of the water. Immediately after, apply the cork D, with the tube AB, to the bottle, and putting it in the situation FG, let the extremity B of the tube pass through the water of the basin into the neck of the bottle K, which now must be kept up with the hand, or other convenient support, as it cannot rest upon the bottom of the basin. The mixture of chalk, &c. in the bottle FG, will immediately begin to effervesce, showing a frothing, and an intestine motion accompanied with heat, that may be felt by applying the hand to the outside of the bottle. The elastic fluid called *fixed air* is copiously emitted from this mixture, and passing through the bent tube, will go into the bottle K, as appears by the bubbles which come out of the tube, and passing through the water, ascend to the top of the inverted bottle. In proportion as the elastic fluid fills the bottle K, the water gradually descends, and at last is quite expelled from it; the bottle K then is filled with fixed air, and being corked under water, may be removed from the basin, and kept for use. Another bottle may then be filled with water, and may be inverted over the extremity of the bent tube in the place of K, which other bottle may be filled in a similar manner, and so on till the mixture in FG has finished to yield any fixed air.

If one of these bottles filled with fixed air be uncorked, and holding it with the mouth upwards, a lighted wax taper, bent like L, or a small piece of it affixed to the extremity of a wire, be immediately let down in it, the flame will be instantly extinguished. The same thing will happen if a lighted piece of wood is let down in it.

Take a clean bowl, and putting the mouth of a bottle, filled with fixed air, in it, uncork it, and keep it in that situation for about a minute. The fixed air being specifically heavier than common air, will come out of the bottle, and will remain at the bottom of the

Air.

Plate
CCCXIII.
fig. 10

Cavallo
on Air

show

Air. bowl, whilst common air enters into the bottle; which bottle may now be removed; and, in order to show the real existence of the fixed air, which will immediately show its being heavier than common air, put a lighted wax taper into the bowl, pretty near its bottom, which taper will be extinguished immediately. The air in this experiment must be agitated as little as it is possible. That the flame of the wax taper was really extinguished by the fixed air, may be easily proved in the following manner:—Blow once or twice into the bowl, by which means the fixed air will be expelled from it; and then, on letting down a lighted wax-taper in it as before, it will be found that it is no longer extinguished, but will burn very well, the bowl being now filled with common air. This experiment never fails of surprising the spectators, as it clearly exhibits two remarkable properties of a fluid, which they can neither see nor distinguish by the feeling.

*Cavetto on
Air.*

When the bottle K is about half filled with fixed air, put a mark with a bit of soft wax on the outside of it, just coinciding with the level of the water in it, and immediately after shake the bottle; but taking care that its mouth be not lifted above the surface of the water in the basin. After having shaken it for about a minute, on intermitting the agitation, it will be found that the water is above the mark; which shows that some of the fixed air has been absorbed by it. Let this absorption be carried on as far as possible, by agitating the bottle repeatedly, and allowing time to let more fixed air be produced and enter into the bottle in proportion as the water absorbs it. Then apply the hand, or a finger, to the mouth of the bottle whilst under water; bring the bottle out, and turn it with the mouth upwards. The water then will be found to have acquired a pleasant acidulous taste. The water thus impregnated with fixed air changes the blue infusion of some vegetable substances into red; so that if a weak solution of heliotrope is mixed with it, or indeed if it is simply exposed to fixed air, the liquor acquires a reddish appearance. It also corrodes iron, and some other metals, much more easily than common water. But the greatest and most useful property of this acidulated water, or water impregnated with fixed air, is its being a powerful antiseptic. As the most used mineral waters are medicinal principally on account of their being impregnated with fixed air, besides which they generally contain some small portion of metal or salt dissolved; they may be imitated by impregnating water with fixed air, and then adding that quantity of salt or of metal, that by analysis the original mineral waters are found to contain.

It is for its great property of hindering putrefaction, that fixed air by itself, or incorporated with various fluids, especially with water; and that vegetables, fugar, and other substances which abound with fixed air, are very powerful remedies in putrid diseases*. Sir John Pringle supposes, with great probability, that the frequent use of sugar and fresh vegetables, which at this time make up a considerable part of the diet of the European nations, prevents those putrid diseases and plagues which formerly were rather frequent.—Dr Macbride, showing experimentally that fixed air is discharged by such substances as form our common food, ascribes the preservation of the body from putrefaction in great measure to the fixed air,

which in the ordinary process of digestion is disengaged from the aliment, and incorporates with the fluids of the body.

From the same property it may be also usefully applied to several economical purposes. Mr Henry found, that fixed air can preserve fruit incorrupt for a considerable time. He tried a bunch of Italian grapes, which being suspended in the middle part of Dr Nouth's apparatus, and being supplied with plentiful streams of fixed air every day, was preserved without any signs of decay for about one month longer than a similar bunch suspended in a decanter containing common air. Strawberries and cherries he also found to be preserved without decay some days longer in fixed than in common air. Indeed, fixed air preserves not only fruit, but resists putrefaction in general. Dr Macbride, in his elegant Essays on Medical and Philosophical Subjects, has published various experiments which demonstrate this property of fixed air. He found, that not only good meat was preserved incorrupt for a considerable time, when exposed to fixed air; but that the putrefaction of substances actually putrid was impeded by this means, and even that those substances were restored from the putrescent to a sound state. That putrefaction was checked by fermentation, was discovered by Sir John Pringle; and Dr Macbride observed, that this effect was owing to the fixed air produced in the act of fermentation. But it must be observed, that when the sound, or even putrid substances, expose a very great surface to the fixed air, as is the case with milk, bile, and other fluids impregnated with fixed air, and also with small bits of meat, then they are preserved for a considerable time; but large pieces of solid animal substances, as for instance roundish pieces of flesh of about half a pound weight, do not seem to remain incorrupt much longer in fixed than in common air; at least the difference is inconsiderable. Sir William Lee, baronet, in two of his letters to Dr Priestley, informs him of his having found, that flesh-meat, even in the hot season, could be preserved wholesome for several days, by only washing it two or three times a-day in water impregnated with fixed air. "We have been enabled," says he, "to preserve meat as perfectly sweet and good to the extent of ten days, as at the first killing; and there seems no doubt it might be preserved much longer." He has even recovered some meat that had begun to change. This useful discovery, Sir William justly observes, may be very beneficial to the public, especially to butchers. "Particularly a butcher," says he, "who deals pretty largely, assures me, he found the greatest success from it, and only objects that the veal was a little discoloured, though kept perfectly sweet."

11. *Inflammable Air* is produced, like fixed air, both naturally and artificially. It is yielded abundantly by putrid animal and vegetable substances, and in general by those inflammable bodies which part easily with their phlogiston. Hence, in caverns and mines, especially in coal-mines, this fluid is often found. Sometimes, when the miners break a piece of the mineral, thereby probably disclosing some hidden cavity, the inflammable air rushes out in great quantity. Being specifically lighter than common air, it always ascends, and escapes through fissures, except in those places

* See Medicine, n^o 458.

ir. which are closely vaulted. Being generally mixed with a considerable quantity of common air, it is less noxious than fixed air; so that the miners breathe it with impunity; though, by reason of its inflammable property, it often produces terrible explosions; from whence the miners have called it the *fire-damp*.

Inflammable air is often produced in ditches, exhaling from the surface of putrid water; in burying-places and houses of office, where putrefying animal or vegetable matters are collected. It may also be extracted from the waters of moat lakes and rivers where, in great quantities of fermentable and putrefying matters are thrown, as in the Thames, Severn, &c. In warm climates this kind of air is produced in much greater quantities, as the processes of fermentation and putrefaction there go on much more rapidly than in colder countries. So rapid is the production of this kind of air indeed in hot climates, that if the mud at the bottom of a pond is well stirred, and a lighted candle immediately afterwards brought near to the surface of the water, the inflammable air will take fire, and a flame instantly spread over the surface of the pond, affording a very curious spectacle in the night-time. Inflammable and fixed air, as also phlogisticated air, are discharged by our aliments in the natural course of digestion, and afterwards discharged from the intestines.

There is scarce any substance from which, by one process or other, inflammable air may not be obtained. But to the inflammable elastic fluids thus obtained, perhaps no other properties in common can be ascribed than those of being inflammable, and being specifically lighter than common air. In other respects they show a material difference between each other, both in weight, smell, power of burning, of preserving their properties, and the phenomena attending their combustion. Hence various species of this fluid might be enumerated. As yet, however, there have not been a sufficient number of observations to enable us to make these distinctions properly. We shall therefore only remark the difference between a real inflammable gas, and that which is evidently formed by mixing a volatile inflammable fluid with the common atmosphere. A drop of ether put into a quantity of common air, diffuses itself by evaporation through the whole, taking fire at the approach of a candle like true inflammable air. In like manner Mr Cigna observes, that air saturated with volatile alkali is inflammable; and Dr Priestley has found, that alkaline air is itself weakly inflammable.

To produce Inflammable Air.

The process for making this sort of gas is the same as that for making fixed air: one of the materials only must be different, viz. iron filings, or grossly powdered zinc, must be used instead of chalk; to which filings some oil of vitriol and water must be added, in the same proportion as in the fixed air, or rather a little more of oil of vitriol.

N. B. Instead of the filings of iron, small nails, or small bits of iron-wire, answer equally well.

The inflammable elastic fluid produced by this mixture, has a displeasing smell, even when mixed with a very large quantity of common air; so that if any considerable quantity of it comes out of the bottle, before the cork with the bent tube be applied to it, &c.

its smell may be perceived all over the room in which the experiment is made; but this smell is not particularly offensive.

When a bottle has been filled with this elastic fluid, stop the mouth of it with your thumb, or any stopper, and taking it out of the basin, bring it near the flame of a candle; and when the mouth of the bottle is very near it, remove the stopper, and the elastic fluid contained in the bottle will be immediately inflamed; and if the capacity of the bottle is nearly equal to four ounces measure, it will continue burning quietly for about half a minute, the flame gradually descending lower and lower, as far as about the middle of the bottle, in proportion as the inflammable gas is consumed.

In this experiment we see, that inflammable air follows the general rule of all other combustible substances, namely, that of burning only when in contact with common air: thus the flame of this gas, whilst burning, is observable only on that surface of it which is contiguous to the common air; so that if the bottle be closed, the flame is put out immediately, because the air is intercepted from it. But if the inflammable air were put in such a situation as to expose a very great surface to the common air, it is plain, that by this means its combustion would be accelerated, so as to let it burn instantly, and go off with an explosion, caused by the sudden rarefaction of the air. In fact, this effect may be easily observed in the following manner: When the bottle is to be inverted into the basin, in order to let it be filled with the inflammable gas, instead of filling it entirely with water, let half of it remain filled with common air; then invert it, and let the other half, which now is filled with water, be filled with inflammable air after the usual manner; and when the bottle is full, remove it in the manner shown above, and approach it to the flame of the candle, by which means the inflammable air takes fire; but now it explodes all at once with a large flame and a considerable report, sometimes breaking the bottle in which it is contained. In this case, the bottle being filled with equal parts of inflammable and common air, these two elastic fluids were mixed together, so that almost every particle of the one touched every particle of the other, and hence the sudden combustion was occasioned. The force of this explosion is so very considerable, that some pistols have been contrived, which are charged with a mixture of air and inflammable gas, and being fired by means of an electric spark, are capable to drive a leaden bullet with great violence. Sometimes those pistols are made of glass (but in this case they are not charged with a bullet), and it is very diverting to show, that pistols are charged and explode by the combustion of an invisible substance.

When a slender pipe is tied to the neck of a bladder, and the bladder is filled with inflammable air, after the manner described in the preceding experiment (viz. when the bladder was required to be filled with fixed air), two very pleasing experiments may be performed with it. First, the inflammable gas may be inflamed by applying the flame of the candle to the extremity of the pipe; and squeezing at the same time the bladder, a stream of fire will be formed in the air, which will last as long as the bladder contains any inflammable air; for this gas coming out of the pipe with violence, will continue inflamed for a considerable

Air.

Cavallo on Air.

way in the air. Secondly, the extremity of the pipe may be dipped into a solution of soap, then removing it from the solution, and squeezing the bladder very gently, a ball of soap-water may be formed, including inflammable air: which ball, on account of the inflammable gas being much lighter than common air, as soon as it is detached from the pipe will ascend upwards, and will break by dashing against the ceiling, contrary to those commonly made by children, which in still air go downwards.—Whilst the ball is ascending, if the flame of the candle be approached to it, the film of soap-water will be instantly broke, and the inflammable air will take fire; thus a flame may be shown to be seemingly produced from a soap-ball.

In flagrant waters where inflammable air is naturally produced, it may, especially in the hot months, be caught in great plenty in the following manner. Fill a wide-mouthed bottle with the water of the pond, and keep it inverted therein; then with a stick stir the mud at the bottom of the pond, just under the inverted bottle, so as to let the bubbles of air which come out of it enter into the bottle: which air is inflammable. When by thus stirring the mud in various places, and catching the air in the bottle until this is filled, a cork or glass-stopper must be put over it whilst standing in water, and then the bottle may be taken home, in order to examine the contained inflammable fluid at leisure.

Heat alone is capable to extract a good deal of inflammable air out of most inflammable substances, even from some of the metals. Dr Hales obtained inflammable air by simply distilling wax, pitch, pease, amber, coals, and oyster-shells. Mr Fontana says he extracted a considerable quantity of inflammable air from spathose iron, by the action of fire only, applied to a matras. But Dr Priestley has obtained it from a vast many more substances. His method is, to introduce the required substance into a gun-barrel, to the extremity of which a tube of glass, or of a tobacco-pipe, was luted, and a flaccid bladder was tied to the end of this tube, which received the elastic fluid produced, when the gun-barrel was put into the fire. The Doctor observes, that in order to get a considerable quantity of inflammable air from various substances, the heat must be applied suddenly. "For," says he, "notwithstanding the same care be taken in luting, and in every other respect, six or even ten times more air may be got by a sudden heat than by a slow one, though the heat that is last applied be as intense as that which was applied suddenly. A bit of dry oak, weighing about twelve grains, will generally yield about a sheep's bladder full of inflammable air with a brisk heat, when it will only give about two or three ounce measures, if the same heat be applied to it very gradually. To what this difference is owing, I cannot tell. Perhaps the phlogiston, being extricated more slowly, may not be entirely expelled, but form another kind of union with its base." When the Doctor wanted to extract inflammable air from metals by means of heat only, he directed the focus of a lens upon them, whilst they were under the exhausted receiver of the air-pump, or were confined by quicksilver.

From pure filings of iron, and of steel carefully fortified with a magnet, and confined by quicksilver in an

inverted glass jar, Dr Priestley, by means of the focus of a lens, obtained some permanently elastic fluid, which, as he observes, was weakly inflammable. In forcing the steel-filings for this experiment, the Doctor observes, that care must be taken not to let any other substance be mixed with them, since the least bit of wood, or any vegetable or animal matter, hardly discernible by the eye, will yield more inflammable air than a considerable quantity of iron-filings. "I found (says he) at this time, that eleven grains of steel-filings, from watch-springs, yielded $\frac{1}{4}$ more inflammable air, than the same weight of iron-filings; which agrees with the hypothesis that steel contains more phlogiston than iron."

By directing the focus of the lens upon filings of zinc or upon brass-dust *in vacuo*, the Doctor obtained an elastic fluid that was strongly inflammable. But from tin he obtained an elastic fluid that was weakly inflammable. With other metallic substances, or with the calx of any metal whatever, the Doctor had no success.

From a mixture of iron-filings and chalk, the Doctor obtained, by means of the lens, a plentiful mixture of fixed and inflammable air, as might be naturally expected.

The elastic fluid expelled from charcoal by heat only, is fixed air; but the residuum of it Dr Priestley found to be inflammable. Mr Fontana had a very elegant way to extract inflammable air from red-hot charcoal. With a pair of tongs he took a piece of charcoal, when thoroughly ignited, and plunging it in water, brought it instantly under a large-mouthed receiver, which was filled with and inverted in the water, in order to collect the bubbles of inflammable air that proceeded from the charcoal in the act of cooling. After the same manner he treated several pieces of charcoal, or the same piece several successive times, until he got a quantity of inflammable air sufficient for his purpose.

By means of heat in a gun-barrel, Dr Priestley obtained from pipe-clay, first inflammable, and then fixed air. But a quantity of inflammable air is obtained, together with fixed air, in various cases, as we have already remarked.

Pit-coal, by distillation, yields inflammable air, which, when fired in a wide-mouthed phial, burns with a bright lambent flame, without explosion.

By exposing to heat, in a gun-barrel, a mixture of calx of zinc and charcoal, or Prussian blue, Mr de Laffone obtained an inflammable air, which burned without explosion.

Dr Priestley found, that when iron-filings and brimstone, moistened with water, were confined by quicksilver, and suffered to ferment in a warm place, some inflammable air was generated. Filings of zinc and brimstone produced the same effect.

By taking electric sparks in any kind of oil, spirit of wine, ether, or spirit of sal ammoniac, Dr Priestley obtained inflammable air. The oil, or other liquor, was confined in a glass tube by quicksilver, and a wire was cemented in the upper part of the tube, through which the sparks being sent, went to the quicksilver through the oil; but after that a few sparks had been taken, a quantity of inflammable air was generated, &c. Left the production of inflammable

Air. air should be attributed to the cement which fastened the wire, the Doctor repeated the experiment with ether in a glass syphon; but the inflammable air was generated as before. This elastic fluid does not lose its inflammability by being passed several times from one vessel into another through water.

Alkaline air, by taking electric explosions in it, is changed into inflammable air.

By means of acids, inflammable air is obtained in greater abundance, and more readily. Iron, zinc, or tin, yield plenty of inflammable air when acted on by diluted vitriolic or marine acids.

If iron is put into strong vitriolic acid, the quantity of elastic fluid that is produced is very little, except heat be applied to the phial, for then the production of elastic fluid is more copious; but this elastic fluid is vitriolic acid air, mixed with a small portion of inflammable air, the proportional quantity of it being less when the acid is more concentrated.

Zinc, treated after the same manner, produces the like effects, except that it gives more elastic fluid, without the application of heat, than iron does; and the greatest part of the produced elastic fluid is inflammable.

In order to obtain the greatest quantity of inflammable air from iron or zinc, the vitriolic acid must be diluted with much water, as about one part of strong oil of vitriol to five or six parts of water. Dr Priestley found, that eleven grains of iron yielded $8\frac{1}{2}$ ounces measures of inflammable air. According to Mr Cavendish, one ounce of zinc, dissolved either in the vitriolic or marine acid, yields a quantity of inflammable air equal to the bulk of 356 ounces of water; one ounce of iron, dissolved by means of vitriolic acid, yields a quantity of inflammable air equal to the bulk of 412 ounces of water; and one ounce of tin yields half as much inflammable air as iron does.

The solutions of iron, tin, copper, lead, and zinc, in the marine acid, produce marine-acid air, and inflammable air, but in various quantities. The proportion of the former to the latter is as one to eight in iron, as one to six in tin, as three to one in copper and lead, and as one to ten in zinc. Regulus of antimony, dissolved in marine acid, with the application of heat, yields a small quantity of elastic fluid, which is weakly inflammable.

Dr Priestley obtained inflammable air, not only by dissolving various substances in marine acid, but also by exposing divers bodies to marine-acid air, which is probably the purest part of the marine acid. Having admitted iron filings to this acid air, they were dissolved by it pretty fast; half of the elastic fluid disappeared, and the rest was rendered unabsorbable by water, and inflammable. The same effect was produced by almost every substance which contains phlogiston, as by spirit of wine, oil of olives, spirit of turpentine, charcoal, phosphorus, bees-wax, sulphur, dry corkwood, pieces of oak, ivory, pieces of roasted beef, and even some pieces of a whitish kind of flint.

A greater or smaller portion of the acid air was absorbed, and the rest sometimes was all inflammable, and often was partly acid air, which was soon absorbed on the admission of water, and partly inflammable. In short, it seems as if this acid air, having a great affinity with phlogiston, separates it from all those substances which contain it even in small quan-

tity, and from that combination becomes inflammable.

By means of nitrous acid, inflammable air may be obtained from various substances containing phlogiston; but it is always mixed with nitrous air, and sometimes also with fixed and common or phlogisticated air. If two parts of spirit of wine, mixed with one part of nitrous acid, are put into a phial with a ground-glass stopple and tube, and the flame of a candle be applied to it, so as to heat it gradually, the inflammable air will be produced very readily; the inflammability of which is, however, not very permanent, for by a little washing in water it may be annihilated. In the solution of most substances in nitrous acid, it generally happens, that the elastic fluid, which is obtained towards the latter end of the process, possesses the property of being inflammable; thus iron, dissolved in nitrous acid, yields nitrous air; but when the nitrous air ceases to be produced, if the heat of a candle be applied to the solution, more elastic fluid will be produced which is inflammable. "The nitrous acid (says Dr Ingenhoufz) when mixed with iron filings in a very diluted state, gives, by the assistance of a moderate degree of heat, a mixture of different airs, partly fixed, partly common air, and partly phlogisticated air."

III. Nitrous Air. This is a permanently elastic fluid, which is never found naturally, like fixed or inflammable air, but is entirely artificial.

This elastic fluid consists principally of nitrous acid and phlogiston; so that it cannot be produced but from that acid, or, which is the same thing, from substances containing the nitrous acid and phlogiston; thus, when the nitrous acid is mixed with metals, or with animal or vegetable substances which contain phlogiston, nitrous air is generally produced; but very little or none of this sort of elastic fluid is yielded when the nitrous acid is mixed with metallic calxes, with pure ashes of vegetable substances, or, in short, with any substance which contains little or nothing of phlogiston. In this case, if the mixture is exposed to a sufficiently strong degree of heat, the nitrous acid is decomposed, and phlogisticated air is produced; though, in some period of the process, a little nitrous air is generally produced, which is owing to the small quantity of phlogiston which exists in most, if not in all metallic calxes, &c.

The variety of elastic fluids obtainable when nitrous acid is employed, may be deduced from observing, that the nitrous acid itself, by being decomposed, may generate dephlogisticated air; that, by joining with the phlogiston of the substance with which it is mixed, may generate nitrous air; that, by the mixture of those two elastic fluids, another elastic fluid, namely, phlogisticated air, may be formed; and that, by its acting as an acid, it may expel one or more other elastic fluids from those substances with which it is mixed.

All metallic substances, when mixed with the nitrous acid, yield nitrous air. Indeed gold, platina, and regulus of antimony, as they are not dissoluble in simple nitrous acid, must be dissolved in aqua regia, in order to obtain nitrous air from them. Although all metallic substances, by means of the nitrous acid, may be made to yield nitrous air; yet they do not produce it in equal quantities, with equal facility, and of equal goodness. The following are the more remarkable particulars relating to this matter:

Either silver, copper, brass, iron, mercury, bismuth,

or nickel, when mixed with nitrous acid, yield nitrous air in great quantities. Some of them, especially mercury, require the aid of heat in order to produce the elastic fluid; the flame of a candle applied to the phial is sufficient; but others, especially copper and iron, do not want the application of any heat. Gold, platinum, and the regulus of antimony, when put in aqua regia, yield nitrous air pretty readily. Among the metals, lead yields nitrous air in the smallest quantity. "I poured (says Dr Priestley) smoking spirit of nitre into a phial with a ground-stopper and tube, containing $1\frac{1}{2}$ ounce measures filled with small leaden shot, so as to leave no common air at all, either in the phial or in the tube; and I placed it so as to receive the air that might come from it in water.

"After waiting an hour, in which little or no air was produced, I applied the flame of a candle, though not very near, to it; and in these circumstances I got about an ounce measure of air: but upon some water rushing into the phial while the candle was withdrawn, air was produced very plentifully. I collected in all about a quarter of a pint; and might probably have got much more, but that the salt formed by the solution of the lead had so nearly closed up the tube, that I thought proper to discontinue the process. The air, both of the first and of the last produce, was of the same quantity; and so far nitrous, that two measures of common air, and one of this, occupied the space of two measures only; excepting that the very first and very last produce, mixed with common air, took up a little more room than that which I got in the middle of the process. When the air was produced very fast, it was exceedingly turbid, as if it had been filled with a white powder."

Among the semi-metals, zinc gives the weakest nitrous air, when dissolved in nitrous acid. The elastic fluid produced from it is mostly phlogificated air. From 4 pennyweights and 17 grains of zinc, dissolved in spirit of nitre diluted with an equal quantity of water, Dr Priestley obtained about 12 ounce measures of very weak nitrous air. It occasioned a very slight effervescence when mixed with common air (c). The Doctor obtained nitrous air even from some flowers of zinc. "Having (says he) mixed a quantity of blue spirit of nitre with flowers of zinc, which were of a dull colour, and appeared from several experiments to contain a portion of phlogiston, it yielded, with the heat of a candle applied to the phial which contained it, strong nitrous air; when the common spirit of nitre, applied in the same manner, gave only phlogificated air; the phlogiston of which came probably from the calx itself, though a small portion of it might have been in the nitrous acid, which I believe is never entirely free from it.

"This experiment also seems to prove, that an earth is the basis of nitrous air; for the same blue spirit of nitre, which gave nitrous air with these flowers of zinc, yielded no air at all when it was treated in the same manner without them."

The quantity of nitrous air that may be obtained from various metals, is difficult to be ascertained, on account of the diversity occasioned by the strength of the acid, the various nature of the metallic substance, and the method of performing the experiments. The following is a table of the produces of nitrous air from various metals, extracted from Dr Priestley's first vo-

lume of Experiments and Observations; but which, as the author himself intimates, is far from being very accurate.

| dwts. | grs. | | |
|-------|----------------|-------------------|---------------------------------|
| 6 | 0 | of silver yielded | $17\frac{1}{2}$ ounce measures. |
| 5 | 19 | of quicksilver, | $4\frac{1}{2}$ |
| 1 | $2\frac{1}{2}$ | of copper, | $14\frac{1}{2}$ |
| 2 | 0 | of brals, | 21 |
| 0 | 20 | of iron, | |
| 1 | 5 | of bismuth, | 6 |
| 0 | 12 | of nickel, | 4 |

The various strength of the nitrous acid produces great diversity in the production of nitrous air. Thus, if copper is dissolved in strong nitrous acid, it will not produce the least quantity of nitrous air; but when dissolved in diluted nitrous acid, it produces a great quantity of that elastic fluid. The strong and pale-coloured nitrous acid should be diluted with at least two or three parts of water to one of the acid, for the easy production of nitrous air from copper and mercury.

The briskness of the effervescence, and the production of nitrous air, are promoted by heat, and also by letting the metallic substance present a great quantity of surface to the acids.

For the generality of experiments, no other degree of heat is required than that produced by the effervescence itself, except mercury be used, which requires the application of some heat. When the metal exhibits a very great surface to the acid, as is the case when filings are used, the effervescence and production of nitrous air are often much quicker than can be conveniently managed.

Copper or brals, when clipped into flat bits, each about two or three grains in weight, and about a quarter of a square inch in surface, and when dissolved in nitrous acid properly diluted, yield nitrous air very equally; but if iron be used, the pieces of it should be larger and fewer; in short, it should present a much less surface to the diluted acid; otherwise the increase of heat in the process, and the rapid production of elastic fluid, render the operation both difficult and dangerous for the operator.

As the nitrous air is mostly necessary to try the goodness of respirable air †, it is of great consequence to make it always of one constant degree of goodness; but this object is answered by dissolving substances of a very homologous nature in the nitrous acid; therefore it is plain, that the metals whose nature is more uniform, must be preferred for this purpose. Accordingly, brals yields nitrous air of a more uniform nature than iron: copper is superior to brals; but pure mercury is still superior to copper: and indeed this is the metal which, considering its nature, uniformity of substance, and easy solution, is upon the whole the most useful for this purpose.

It has been generally observed, that solid vegetable substances, when dissolved in nitrous acid, yield more nitrous air than the animal substances, though this nitrous air is not so pure as that obtained from metals.

Sometimes it contains some fixed air, and a good deal of inflammable air, which is mostly produced towards the end of the process. On the other hand, the nitrous air extracted from animal-substances generally contains a good deal of phlogificated air, and sometimes some fixed air. In order to obtain nitrous air

from

(c) Mr de Laffone says, that zinc, when dissolved in nitrous acid, yields fixed and not nitrous air.

† See Experiment 1010.

Air. from the solution of animal and vegetable substances in nitrous acid, often some degree of heat must be applied to the phial. The acid also sometimes must be very concentrated, and in other cases it must be diluted; but it is hardly worth while, or practicable, to determine with exactness all those particular cases.

To make Nitrous Air.—The metal, viz. copper, brass, or mercury, is first put into the bottle, (which, as well as the whole process, is the same as that described for *fixed Air*), so as to fill about one-third of the same; then some water is poured into the bottle, so as just to cover the metal-fillings; and lastly, the nitrous acid is added, the quantity of which, when strong, should be about one-third or half the quantity of the water. The smell of the nitrous gas is very penetrating and offensive, and occasions a red smoke as soon as it comes into contact with the common air; hence, whenever any of it escapes from the bottle, it may be observed not only by the smell, but also by the slight red colour.

In order to observe the principal property of this elastic fluid, which is that of diminishing the bulk of common air, let a glass tube, closed at one end, and about nine inches long, and half or three quarters of an inch in diameter, be filled with water, and inverted in water; then take a small vial, of about half an ounce measure, filled with common air, and plunging it under the water contained in the same basin where the inverted tube is kept, let that quantity of air enter into the tube, which will go to the top of it, the water subsiding accordingly. Let a mark be made, either with a file or by sticking soft wax on the tube, just opposite to the surface of the water in it, which will mark how much of the tube is filled by that given measure of air. After the same manner, fill the same small vial (which we shall call the *measures*) again with air; throw that air into the tube, and put a mark on the tube coinciding with the level of the water in it. In this manner let four or five measures be marked on the tube. Now, if three measures of common air are put into this tube, when filled with water and inverted, they will fill a space of it as far as the third mark. The same thing will happen if three measures of nitrous instead of common air are put in it; but if two measures of common air and one measure of nitrous air, or one measure of the former and two of the latter, are introduced in it, they will fill a space much shorter than the third mark. On the moment that these two kinds of elastic fluids come into contact, a reddish appearance is perceived, which soon vanishes, and the water, which at first nearly reaches the third mark, rises gradually into the tube, and becomes nearly stationary after about two or three minutes; which shows that the diminution is effected gradually. See *Eudiometer*, and *AIR*, n° 39. (*Encycl.*)

IV. *Dephlogisticated AIR*. This is no other than exceedingly pure atmospheric air, entirely free from those heterogeneous vapours which contaminate the air we commonly breathe. The easiest method of procuring some of this air is to put some red-lead into the

bottle, together with some good strong oil of vitriol, but without any water. Let the red-lead fill about a quarter of the bottle, and the vitriolic acid be about the same quantity, or very little less; then apply the bent tube to the bottle, and proceed in the same manner as above. But it must be remarked, that without heat this mixture of red-lead and vitriolic acid will not give any dephlogisticated air, or it yields an inconsiderable quantity of it; for which reason the flame of a candle (that of a wax-taper is sufficient) must be applied under the bottom of the bottle; which for this purpose must be rather thin, otherwise it will be easily cracked (D). In this manner the red-lead will yield a good quantity of elastic fluid, the greatest part of which is dephlogisticated air; but not the whole quantity of it, for a good portion of fixed air comes out with it. In order to separate the fixed from the dephlogisticated air, the inverted bottle, when filled with the compound of both, as it is emitted from the red-lead, must be shook in the basin, for impregnating water with fixed air; by which means the water will absorb the whole quantity of fixed air, and leave the dephlogisticated air by itself.

From the first experiments by which this kind of air was produced, Dr Priestley concluded, that the nitrous acid and earth were essential ingredients in its composition †. This theory, however, seems to be † See *AIR*, (*Encycl.*)
n° 44.
overthrown by subsequent experiments, where the purest dephlogisticated air was produced from substances in which no nitrous acid could be supposed to exist. The abbe Fontana having rendered some red precipitate very dry by keeping it in a small degree of heat for several hours, weighed 192 grains of it, and introduced this quantity into a glass vessel proper for expelling the air from it. Applying, then, a sufficient degree of heat under it, he received the air into a glass-jar filled with quicksilver, and inverted into a vessel of the same. Thus he procured $26\frac{1}{2}$ cubic inches of very pure dephlogisticated air, the mercury being at the same time revived, and losing 13½ grains of its weight, which is nearly the whole weight of the air emitted by it. By a similar process, red-lead also emits a very pure kind of air; and it is remarkable, that red-lead which has been kept for a long time, yields more dephlogisticated air than such as is new; the reason of which Mr Cavallo supposes to be, that red-lead, when newly made, is not such a pure calx as after it has been kept for some time. From sedative salt also, from manganese, lapis calaminaris, and all the vitriols, pure dephlogisticated air has been obtained; nor was it produced from the native vitriols, which might perhaps have been suspected to contain some nitre; but from iron, copper, and zinc, dissolved directly in pure vitriolic acid. Mercury dissolved in the vitriolic acid, distilled to drincks, and the residuum urged with a strong heat, yields first a quantity of vitriolic acid air mixed with fixed air, and then dephlogisticated air. “It is remarkable (says Dr Priestley) that, either by means of oil of vitriol or spirit of nitre, mercury yields a very great quantity of dephlogisticated
45 K 2 air;

(D) In this operation the flame of the candle, when once applied, must be kept continually near it; and when the mixture does not produce any more elastic fluid, or the operation is required to be intermitted, care should be taken to remove the extremity of the bent tube from the water first, and then to take off the flame of the candle from under the bottle; otherwise, if the flame of the candle be first removed, the materials within the bottle condensing by cold, the water immediately enters, which in an instant fills the bottle, and generally breaks it.

air; but with this difference, that in the process with spirit of nitre, almost the whole of it (that is, if the process is conducted with care, with the loss of not more than the 20th part of the mercury) is revived, and therefore may be used again and again; whereas in the process with the oil of vitriol, almost all the mercury is lost." By mixing the same acid with manganese also, dephlogisticated air was obtained. Mr Cavallo mentions one instance where dephlogisticated air was produced by means of the muriatic acid; but in this he seems to have mistaken Dr Priestley, whose authority he quotes. Minium, as already mentioned, yields a quantity of dephlogisticated air by heat, without any addition; and it seems to have been only this air which was set loose by the acid, and not any original production. His words are: "Spirit of salt, I have observed, dissolves a great quantity of minium. In order to discover what became of the air it contains, I distilled a quantity of that solution, which was of a yellow colour, made by the first affusion of the acid. When the solution became hot, it yielded a quantity of fixed air, so as to make lime-water turbid only in the slightest degree. As it boiled, no air at all was procured, nor when it was distilled to dryness. I treated in the same manner a saturated solution of white minium, made so by its colour having been discharged by a previous affusion of the acid. But this solution yielded no air at all from the beginning to the end of the process; nor was the common air in the retort phlogisticated either at the beginning or end."

From every experiment it appears, that dephlogisticated air, if it could be readily obtained, and at a cheap rate, would be a most valuable manufacture. The heat communicated by means of it to burning fuel is incredible. When a lighted candle is introduced into a phial containing dephlogisticated air, its flame not only grows larger, but becomes exceedingly bright. When the dephlogisticated air is very pure, the candle burns with a crackling noise as if the air contained some combustible matter, and wastes the wax or tallow surprisingly fast: the heat of the flame is also very intense. But the best method of observing its intensity is the following: Fill a bladder with dephlogisticated air, then fasten a glass tube to the mouth of the bladder: the outward aperture of this tube must be drawn to a fine point like that of an ordinary blow-pipe; then holding the extremity of the tube near the flame of a large candle or of a lamp, press the bladder so as to force the dephlogisticated air out through the small aperture of the tube, which will drive the flame of the candle into an horizontal direction, augmenting its force prodigiously; so that if small bits of any metal, held upon a piece of charcoal, or upon a piece of broken crucible, are presented to the apex of that flame, they will be presently melted. Even grains of platina may be melted by these means. The heat of other fuel is equally increased by blowing dephlogisticated air into it. "I put (says Dr Priestley) a quantity of Mr Bewley's pyrophorus into one of the small jars which I use for experiments on air in quicksilver, I inverted it in a basin of the same, and threw up dephlogisticated air at different times. It always occasioned a sudden and vehement accession, like the flashing of gunpowder; and the air was greatly diminished, as might have been foreseen." When mixed with in-

flammable air, and the mixture is brought near any flaming substance, or when an electric spark is sent through it, a great explosion ensues. If an ounce glass vial, which for this experiment should be very strong, be filled with a little more than one-third dephlogisticated, and the rest inflammable air, when the flame of a candle is presented to its mouth, it will explode nearly as loud as a small pistol.

It is not, however, only the advantages which might result from such an increase of heat that are expected from dephlogisticated air. It has been found by experience, that animals will live much longer in this kind of air than in an equal quantity of common air; whence it is supposed, that the breathing of it must be much more healthy, and contribute to longevity much more than the common atmosphere. Nay, there are not wanting some who attribute the longevity of the Antediluvians to the great purity of the atmosphere at that time; the whole mals being afterwards tainted by the deluge, in such a manner that it could never regain its former purity and salubrity. But all this as yet is mere conjecture; and excepting the single fact, that animals live much longer in a quantity of dephlogisticated than of common air, there is no evidence that the former contributes more to longevity than the latter. Dr Priestley even throws out a conjecture, that the use of dephlogisticated air might perhaps wear out the system much sooner than common air, in the same manner as it consumes fuel much faster than common air. The great quantity, however, even of the purest air, which is requisite to support animal life, and the expence and trouble of the most ready methods of procuring it, have hitherto prevented any fair trial from being made. Yet philosophers, considering the probability there is of this kind of air being salutary in many diseases, have bestowed some pains in attempting to find out methods of procuring it easily and in large quantity; concerning which we have the following observations in Cavallo's Treatise on Air.

"A man makes in general about 15 inspirations in a minute, and takes in about 30 cubic inches of aerial fluid. But the air which has been once inspired is not thereby much injured, and it may be respired again and again; so that, upon a very moderate calculation, and as appears from actual experiments often repeated, we may safely assert, that a person can breathe 400 cubic inches of good ordinary atmospheric air, at least 30 times, without any inconvenience, *i. e.* it would serve for two minutes; after which that air, though much depraved, is still in a state of being breathed, but then it would occasion some uneasiness. Now, supposing the dephlogisticated air employed to be four times more pure than common air, 400 cubic inches of dephlogisticated air would serve for at least 120 respirations, or eight minutes.

But supposing that 30 inches of common air are completely phlogisticated by a single inspiration, and changed for such as is quite fresh, which indeed is the case in common respiration, then 450 cubic inches of common air will be requisite for one minute's respiration, and 27,000 for one hour; and as dephlogisticated air is supposed to be four times as good, the same quantity of it will serve for four hours. Indeed, if we could depend on the assertions of Mr Fontana, that

Air. by adding lime-water to absorb the fixed air produced by respiration, an animal can live 30 times as long as without it; no doubt a much smaller quantity would serve."

But it is certain such assertions cannot be true; because, though the fixed air should be absorbed as soon as produced, the remaining quantity would still be contaminated by phlogiston. Nay, we are informed by Dr Priestley, who repeated Fontana's experiments, that animals *will not* live longer in a quantity of dephlogisticated air when it stands in contact with lime-water, than they will when no lime-water is used *. In what manner a difference so enormous can take place, between philosophers in other respects so accurate, we can by no means determine. It is plain, however, that if 27,000 inches of common air are necessary for a person in one hour, the same quantity of dephlogisticated air cannot be breathed longer than four hours, nor even so long, with any real advantage. Mr Cavallo indeed allows only 12,000 inches for four hours; but though this might no doubt sustain life for that time, the person must certainly expect nothing from it superior at least to the common atmosphere, if he was not materially injured by it.

A very ready method of procuring dephlogisticated air in large quantity, is by means of nitre; and on the supposition that 12,000 inches are sufficient for four, (or for 40 hours, as he limits the abbe Fontana's supposition), he proceeds in the following manner: "The instruments necessary for the production of dephlogisticated air from nitre are the following; viz. earthen retorts, or earthen vessels with a straight neck, somewhat in the shape of Florence flasks, but with a longer neck, these being cheaper than the retorts, and answering as well;—a small furnace, in which the earthen retort must be kept red-hot; a common chimney-fire is not sufficient. These furnaces may be very easily made out of large black-lead crucibles. The nitre must be put into the retort or other vessel, so as to fill half or nearly three quarters of its belly; then a bent glass tube is luted to the neck of the earthen vessel, in such a manner as not to let any elastic fluid escape into the open air. The best lute or cement for this or similar purposes is made by mixing together whiting and drying oil. The retort being put into the furnace, must be surrounded with lighted charcoal, which is to be supplied according as it wastes: in short, the belly of the retort must be kept quite red-hot, or rather white-hot, for about three hours at least. If, instead of the retort, the other described earthen vessel be used, care should be had to place it with the neck as little inclined to the horizon as possible, lest the nitre should stop the neck and break it." The air is then to be received into large glass-jars, as is usual in other experiments on air.

"The retort or other earthen vessel that is used for this purpose cannot serve for more than once, because it generally breaks in cooling; and besides, the decomposed nitre cannot easily be taken out of it. The retort capable of holding a pound of nitre (the quan-

ty necessary for producing 12,000 cubic inches of dephlogisticated air) for this operation, costs at least half-a-crown; the other earthen vessels in the shape of Florence flasks, but with longer necks, cost about 18d. a-piece or 2s.; so that the price of these vessels forms a considerable part of the expence. If glass vessels are employed, the nitre will not yield near so much air, though of a purer sort, because the glass vessels cannot endure such a great fire as the earthen ones. The retorts of metal, or at least of those metals which are most usually employed for this purpose, viz. iron and copper, phlogistate in a great measure the air as soon as produced. Considering, then, all these circumstances, it appears, that when a person has all the usual apparatus and furnace, the expences at present necessary in London for the production of 12,000 cubic inches of dephlogisticated air, viz. the price of one pound of nitre, of an earthen retort or other vessel, and of charcoal, amount to about 4 s. or 4 s. 6 d.

Another method of preparing dephlogisticated air is, by blowing that of the common atmosphere thro' melted nitre. In this process the phlogiston contained in the atmosphere is gradually consumed, by detonating with the acid of the nitre, and therefore issues much more pure than before. This method has the appearance at first of being much easier and more commodious than the former; but as it is impossible to mix the atmospheric air so exactly with the melted nitre that every particle of the one may come in contact with every particle of the other, it is plain that the former method must be preferable; not to mention that it will be found exceedingly troublesome to blow the air through the nitre, as the latter will be perpetually apt to cool and concreate into lumps by the cold blast.

V. *Vitriolic Acid Air*. This consists of the vitriolic acid, united with some phlogiston which volatilizes, and renders it capable of assuming the form of a permanently elastic fluid. To obtain it, some strong concentrated vitriolic acid must be put into the usual bottle, together with some substance capable of furnishing phlogiston. Olive oil answers very well. The oil of vitriol should be about three or four times as much as the sweet oil, and both together should fill about one-third or half the bottle. A gentle degree of heat is then required, in order to let these materials yield any elastic fluid; which may be done by applying the flame of a wax-taper, as directed above for the production of dephlogisticated air.

This elastic fluid has no action upon quicksilver, but is easily, and in great quantity, absorbed by water; so that if a small quantity of water be introduced into the receiver containing it, and inverted in quicksilver (s), the whole quantity of the acid air disappears, being absorbed by the water; from which it escapes very easily when exposed to the open air. The water thus impregnated acquires the properties of the volatile or sulphureous vitriolic acid.

A piece of camphor introduced into a receiver containing this kind of elastic fluid, is easily dissolved, but by the addition of water the camphor is again recovered.

If

(s) In order to introduce water, or any other fluid, into a receiver inverted in quicksilver, let a small phial be quite filled with that liquid; then holding it with the hand, stop its mouth with a finger, and thus plunge it into the quicksilver, and pass it under the inverted receiver, where being unstoppered, and turned with the mouth upwards, the contained fluid will instantly ascend to the top of the quicksilver in the receiver, on account of it being specifically lighter than quicksilver.

Air.

If a piece of charcoal is admitted to this vitriolic acid gas, it absorbs a good quantity of it, and acquires from it a disagreeable and pungent smell. It is remarkable, that this elastic fluid does not act upon iron; whereas the water combined with it is a powerful solvent of that metal.

VI. *Marine Acid Air*, is no other than the marine acid itself, which without any addition becomes a permanently elastic fluid. In order to procure it, put some sea-salt, or common kitchen-salt, into the usual bottle in which the materials for producing elastic fluids are generally put, so as to fill about a fourth-part of it, and upon this salt pour a small quantity of good concentrated vitriolic acid; then apply the bent tube to the bottle, and introduce it through the quicksilver into the receiver, filled with and inverted in quicksilver, after the usual method, and the elastic fluid, called *marine-acid air*, is copiously produced.

A small quantity of water introduced into a receiver, containing this sort of elastic fluid, absorbs instantaneously a prodigious quantity of it, and becomes a very strong marine acid spirit; indeed, much stronger than can be obtained by any other means.

If any metallic, or in general any inflammable substance, capable of furnishing a considerable quantity of phlogiston, as spirit of wine, oil, &c. be introduced into a receiver filled with this elastic fluid, it occasions a remarkable change; viz. the marine acid air, by acting on it, will be changed into an inflammable elastic fluid, that takes fire by the contact of ignited bodies.

When a small quantity, as for instance, about a fourth-part, of marine acid air is mixed with one part of common air, and a lighted candle is introduced into the receiver containing this mixture, the flame of the candle acquires a beautiful green or bluish colour.

VII. *Nitrous Acid Air*. The elastic fluid, called *nitrous acid air*, may be obtained from heated nitrous acid, the vapour of which acquires a permanent elasticity, and it has been found to remain undecomposed into a visible fluid by the cold to which it has been hitherto exposed. The great difficulty, is to find a fluid capable of confining this acid air, because it is easily and abundantly absorbed by water, which is one of its properties by which it differs from nitrous air. It acts upon quicksilver, and also upon oils: hence its examination cannot be made but very imperfectly; for substances must be exposed to it, or mixed with it, whilst it is actually changing its nature by acting on the mercury or other fluid that confines it.

When water has absorbed a good quantity of this elastic fluid, it acquires the properties of nitrous acid; and when heated, it yields a large quantity of nitrous air, viz. a quantity many times greater than that which water is wont to imbibe of it by agitation, or by any known means.

When the nitrous acid air is combined with essential oils, a considerable effervescence and heat is produced, nearly in the same manner as when the nitrous acid itself is poured upon those oils.

VIII. *Fluor Acid Air*. Put some of those minerals called *fluors*, or *fusible spars*, pulverized, into the usual bottle, and upon it pour some concentrated oil of vitriol; then adapt the bent tube, &c. The fluor acid air is at first produced without the help of heat; but in a short time it will be necessary to apply the flame of

a candle to the bottle, by which means a considerable quantity of this elastic fluid is obtained.

The properties of fluor acid air are nearly the same as those of the vitriolic acid air; hence some excellent philosophers are of opinion, that those two acid airs are essentially the same. The principal, if not the only property by which they are distinguished from each other, is, that when water is admitted into a receiver containing fluor acid air, the water absorbs only a part of it; for a stony crust is formed upon the surface of the water which hinders the farther absorption, and which must be broke before the water absorbs any more of it.

IX. *Alkaline Air*. Let the usual bottle be about half filled with volatile spirit of salt ammoniac; and after applying the bent tube, &c. let the flame of a candle be brought under the bottle, by which means the alkaline air will be produced copiously.

If a small quantity of water is introduced into the receiver filled with this elastic fluid, the whole quantity of it is readily absorbed by the water, which thereby becomes a strong volatile alkaline spirit. If some of this gas is introduced into a receiver containing either the marine or the vitriolic acid air, a white cloud is instantly formed, and the two invisible elastic fluids, losing at once their elasticity, form a visible substance, namely, concrete ammoniacal salts.

The properties of this air are, that it is permanently elastic and unchangeable when confined in vials perfectly dry; but on the approach of moisture, it is instantly absorbed in great quantity without leaving any residuum. There is, however, a point of saturation betwixt it and water, nor can the latter be made to imbibe more than one-third of its weight of alkaline air. When the barometer is at a mean height, alkaline air is specifically lighter than common air in the proportion of 7 to 15, and its elasticity is greater in the proportion of 475 to 132 *. It destroys animal life, and extinguishes fire, though in certain cases it has itself a degree of inflammability †. When a burning candle is put into a jar full of this air, it is indeed extinguished; but just before it goes out, the flame is enlarged by the addition of another of a pale yellow colour. Sometimes it will actually take fire when the flame of a candle approaches it, a weak flame being observed to spread considerably around the candle, and even through the whole body of the alkaline air. By the electric spark it is augmented in bulk, sometimes to $\frac{1}{2}$ more than it was before, and then becomes strongly inflammable air, without the least appearance of volatile alkali. The electric sparks taken in it are red. It dissolves ice almost as readily as a hot iron, even in a very severe cold. It does not act on copper in its dry state, though it does so remarkably when united with water. It readily unites with all the acid airs, forming with them ammoniacal salts according to their different natures. Dr Priestley made two sets of experiments to determine the quantity of these gases necessary to saturate each other; but they vary so much in their result that little dependence can be placed on them. They are as follow:

First Set of EXPERIMENTS.

| | Measures. |
|------------------------------------------------------------|-----------|
| One measure of marine acid air absorbed of alkaline air, 1 | |
| One of vitriolic ditto, | 2 |
| | One |

Air.

* See Vol.
CAND,
(Encycl.)

LATILE
ALKALI,
(Encycl.)

| Air. | Measures. |
|----------------------------------------------------------------------|-----------------|
| One of fluor acid air, | 2 |
| One of nitrous air, | 5 |
| One of fixed air, | 3 |
| Second Set. | |
| One measure of fluor acid air saturated of alkaline ditto, | 1 $\frac{1}{2}$ |
| One of vitriolic acid air, | 2 |
| One of marine acid air, | 1 $\frac{1}{2}$ |
| One of fixed air, | 1 $\frac{1}{2}$ |

The last set, however, the Doctor looks upon as less accurate than the foregoing.

TABLE of the Specific Gravities of the different Elastic Fluids.

| Names of elastic Fluids. | Their specific gravities. | Weight of a cubic inch of, in grains. |
|--------------------------|---------------------------|---------------------------------------|
| Common air, | 152 | 0,385 |
| Dephlogificated air, | 160 | 0,042 |
| Phlogificated air (r), | 140 | 0,377 |
| Fixed air, | 220 | 0,57 |
| Inflammable air, | 10 | 0,035 |
| Nitrous air, | 157 | 0,399 |
| Marine-acid air, | 243 | 0,654 |
| Vitriolic-acid air, | 300 | 0,778 |
| Fluor-acid air, | 450 | 1,24 |
| Alkaline air. | 70 | 0,2 |

X. *Hepatic Air*. A new kind of elastic fluid discovered by Mr Bergman. He obtained it from a mineral called *pseudo-galina nigra Dannemorensis*, an ore of zinc; and it has also been obtained from some other ores of this semimetal. One hundred parts of this mineral were found to contain 29 parts of sulphur, one of arsenic, six of water, six of lead, nine of iron, 45 of zinc, and four of siliceous earth. When oil of vitriol is poured upon this mineral, the hepatic smell is immediately perceived, and a small quantity of hepatic air is produced. Marine acid expels a much greater quantity of hepatic air from this mineral than the vitriolic. By means of diluted nitrous acid, nitrous air only was obtained. No other property of this kind of air is known, but that it deposits a quantity of sulphur when mixed with nitrous air.

Circulation of Air in Rooms. To render the circulation of air sensible, let the air of a room be heated by a strong fire, whilst the air of a contiguous room is cold; then let the door between these two rooms be opened, in which case the hot air of one room being lighter, will pass through the upper part of the opening of the door into the cold room; and, on the contrary, the cold air of the other room being heavier, will pass into the former room through the lower part of the opening; accordingly, it will be found, that applying a lighted candle at the top, in the middle, and at the lower part of the opening between the two rooms, a strong current of air will appear to pass from the hot into the cold room near the top; a contrary current of air will appear to pass from the latter into the former room near the lower part of the said opening; whilst in the middle there is little or no motion at all, as may be clearly perceived by the direction of the flame of the candle.

It is for the same reason that when the fire is lighted

in a chimney, a strong current of air is occasioned to enter the room, which may be felt by applying the hand near the key-hole, or other such small openings, if the doors and windows are shut; for the air over the fire being heated, becomes lighter, and ascends into the chimney, consequently other colder air must supply its place, which forces its way through all the small openings it can find. Were a room with a fire in it to be perfectly closed, excepting the chimney, the air in it would soon become unwholesome for respiration, and the fire would be soon extinguished, besides other inconveniences. Hence it appears, that those persons mistake who expect to keep the air of a room sweet and wholesome, especially for convalescents, by accurately stopping all the smallest openings that admit fresh air. When the current of air that enters into a room is on one side of it where it falls immediately upon the persons who sit in the room, then it may be offensive, especially to delicate constitutions. In that case, such opening should be closed; but at the same time another opening should be made for admitting fresh air, in another more convenient part; for a circulation of air, especially in rooms where a fire is kept, is not only salutary and useful, but is absolutely necessary.

In an ingenious publication, intitled *A Practical Treatise on Chimneys*, there are the following remarks relating to the properest method of admitting air into a room, and of expelling the contaminated air. The author, directing to make a vent-hole near the top of the room, in order to expel the heated and contaminated air, "this," says he, "might be done by means of a small tube opening into the room, either in or near the ceiling; which might either be carried to the top of the building, or be made to communicate with the external air by a small perforation through the wall at the roof of the room; by means of either of which, a proper circulation would be established, and the foul air be carried off.

"For the fire would no sooner have warmed any particles of air within the room, than these would be greatly expanded, and rise immediately upwards, so as to fill the higher parts of the room with rarefied air; and as other particles would be successively heated and rarefied in their turn, by their expansive force they would press upon the sides of the apartment in every place, so as to force the lightest particles through the opening left for that purpose in the top of the room; by which means the foulest air would be gradually drawn off, without defending again into the lower regions to the annoyance of the company."

But in order to admit fresh air into the room, "Let," says he, "another opening be made in the ceiling of the room, having a communication with a small pipe that should lead from thence either to the outside of the wall, or to any other part of the building that might be judged more convenient, where it should be bent, and conducted downwards, till it reached the ground; where it should be left open, to communicate with the external air.—In this situation the cool external air would be forced in at the lower opening of the tube, and made to ascend into the apartment in proportion to the quantity that escaped towards the higher regions by means of the ventilator. And as that weighty air would.

(r) The air was phlogificated by saturation with nitrous air.

Air.

would no sooner enter the room, than it would tend towards the floor by its own natural gravity, it would gradually mix with the heated air in its descent—become, in some measure, warmed by that means, and equally dispersed through the room, so as slowly and imperceptibly to reach the candles and the company in the room, and supply them with a sufficient quantity of fresh and wholesome air, without the inconveniences to which the company are subjected by the usual way of admitting fresh air (c). For if it enters near the floor of the apartment, it is hurried along in a rapid undivided stream towards the fire-place, and striking upon the legs and inferior parts of the body, affects them with a strong sensation of cold. To overcome the effects of this, large fires must be kept; by which other parts of the body are warmed to an extraordinary degree, which is productive of most of those disorders that are pernicious to the young, and often prove fatal to the old, during the winter-season, in these cold regions.

“ Thus might our apartments be kept constantly, and moderately, and equally warm, at a moderate expence, without endangering our health on the one hand, by respiring a confined, stagnant, and putrid air, or, on the other hand, by subjecting ourselves to such danger of catching colds, consumptions, and rheumatic complaints, by being exposed to such exceedingly unequal degrees of heat and cold, as are unavoidable where our apartments are so open as to admit a ready passage to the external air during the winter-season.

“ The reader will easily perceive, that all that has been here said has a reference only to those apartments in cold climates, and rigorous weather, where fire to warm them becomes necessary. In warmer regions, or during the summer-season, there can be no objection to the wheel-ventilator in the window.—It is a simple contrivance, and a safe and effectual mean of preserving the air in our apartments sweet and wholesome at that season.”

It is a vulgar error among many people, to believe that fire purifies the contaminated air, by destroying the noxious particles mixed with it; and for this reason they think, that the fire kept in a room where the air is tainted, purifies the room, by rendering the air in it again fit for respiration. Indeed, a fire kept in a room or apartment where the air is tainted, as is the case with hospitals, goals, and the like, does certainly purify the apartment, and the practice is very useful; but this effect is only because the fire promotes the circulation of the air, and dries the dampness of rooms, furniture, &c.: so that it is not the infected air that is purified, but is new, fresh, and wholesome air, that by the action of the fire has taken the place of the infected air; which infected air, being rarefied by the heat,

has been expelled from the apartment. Fire and combustion in general is so far from purifying contaminated air, that it actually contaminates a prodigious quantity of it in a short time; so that not only a common fire, but even a lighted candle, when kept in a well-closed room, wherein the external air has not a free access, instead of purifying, renders the air of that room noxious.

Instrument for ascertaining the Wholesomeness of Respirable Air. See *EUDIOMETER*.

Air Balloons. A general name for bags of any light substance filled with inflammable air or other permanently elastic fluid, whose specific gravity is considerably less than that of common atmospheric air. The consequence of their being filled in this manner is, that, if they are of any considerable magnitude, they ascend in the air to an amazing height, and will not only ascend in this manner by themselves, but carry up great weights along with them; remaining in these elevated regions till the fluid escapes, either by bursting the bag in consequence of part of the external pressure being removed, or by its gradual evaporation through the pores.

By this invention, the schemes of transporting people through the atmosphere, formerly thought chimerical, are realized; and it is impossible to say how far the art of aerial navigation may be improved, or with what advantages it may be attended. In the last century, a scheme of navigating the atmosphere was proposed by Mr Hook, very much resembling that of air-balloons; but which did not succeed, because he was unacquainted with any vapour possessing equal elasticity with the common air, and less specific gravity. His project was to have a very large copper-globe, so thin, that when it was exhausted of air it would be specifically lighter than an equal bulk of the common atmosphere. Hence it would ascend, and carry up bodies along with it. But it is easy to see that an invincible objection lay against this scheme from the pressure of the external atmosphere, which would not fail to crush such a large globe made of such thin materials.—Though inflammable air, and its great inferiority in specific gravity to common atmospheric air, has been known for several years, yet we hear of no attempts to construct air-balloons till, in the year 1782, Mr Cavallo attempted to make paper bags and bladders, filled with inflammable air, ascend; but failed, the former being permeable to inflammable air, and the latter being too weighty in proportion to their bulk. Had he thought of varnishing his paper, or making bags of gold-beaters skin, he would certainly have succeeded.

The honour of this invention, however, is unquestionably due to the brothers Stephen and Joseph Mont.

(c) Such readers as have been little accustomed to speculations of this sort, will be at a loss to comprehend in what manner two holes, both of them in the roof of the room, and communicating with the air, without any valve, or other contrivance, for opening or closing of themselves, should yet answer the two very opposite purposes; one, of constantly bringing cool air into the room without emitting any warm air—and the other, of as constantly emitting warm and admitting no cool air. They will please to advert, that the one of these tubes communicates with the atmosphere at the bottom of the house, and the other towards the top: the opening of the one is beneath the level of the room, that of the other above it. Now, as the air is more dense at the surface of the ground than at any height above it, the warm rarefying air will naturally issue at that opening where it meets with least resistance, which must invariably be through that which opens to the external air at the greatest height; and as the cool air will naturally be pressed into the room by that opening where the air is most weighty, this must invariably be by that which is nearest the surface of the earth.

Air.

Air. Montgolfier, proprietors of a considerable paper-manufacture at Annonay, a town in the Vivarais, about thirty-six miles south of Lyons: and their invention is the more to be admired, as it is not the effect of the late discovery of a permanently elastic fluid lighter than the common air, but of properties of matter long known, and in the hands of the many acute philosophers of this and of the last century. They conceived, that the effect they looked for might be obtained by confining vapours lighter than common air, in an inverted bag or covering, sufficiently compact to prevent their evaporation; and so light, that, when inflated, its own weight, added to that of the inclosed vapour, might fall somewhat short of the weight of the air which its bulk displaces.

On these principles, they prepared matters for an experiment. They formed a bag or balloon of linen cloth, lined with paper, nearly spherical, and measuring about 35 feet in diameter; its solid contents were about 22,000 cubic feet, a space nearly equal to that occupied by 1980 lb. of common air, of a mean temperature, on the level of the sea. The vapour, which, by conjecture, was about half as light as common air, weighed 990 lb. The balloon, together with a wooden frame suspended to the bottom, which was to serve as ballast, weighed 490 lb.; whence it appears, that the whole must have been about 500 lb. lighter than an equal bulk of common air. This difference of specific gravity, by which these bodies are made to rise, we shall henceforth, without warranting the propriety of the expression, call their *power of ascension*.

The 5th of June 1783 was fixed on for the display of this singular experiment. The states of Vivarais, who were then assembled at Annonay, were invited to the exhibition. The flaccid bag was suspended on a pole 35 feet high; straw and chopped wool were burnt under the opening at the bottom; the vapour, or rather smoke, soon inflated the bag, so as to distend it in all its parts; and, on a sudden, this immense mass ascended in the air with such a velocity, that in less than ten minutes it appeared to be about 1000 toises above the heads of the spectators. A breeze carried it about 1200 toises from the spot whence it departed; and then the vapour, either escaping through some loop-holes that had been accidentally left in the construction, or being condensed by the coldness of the circumambient air, the globe descended gradually on a vineyard, with so little pressure, that none of the flakes were broken, and scarce any of the branches of the vines bent.

The rumour of this successful experiment soon reached the metropolis, and roused the emulation of the Parisian philosophers. Without waiting for particular instructions from the inventors, they reflected on a method of their own; and resolved, instead of vapour, to use inflammable air; the specific weight of which, when pure, they knew to be to that of common air nearly as ten to one.

The process of producing this air being very expensive, a subscription was set on foot; and a sufficient sum being soon raised, M. Charles, professor of experimental philosophy, and M. Robert a mathematical-instrument maker, were set to work: and they constructed a globe of lutestring (taffetas), glazed

over with elastic gum dissolved in some kind of spirit or essential oil. After many difficulties and disappointments, which will ever attend first essays, they succeeded in two days to fill this globe with inflammable air, produced from 1000 lb. of iron-sfilings, and 498 lb. of vitriolic acid, diluted in four times its quantity of water. This globe measured 12 feet 2 inches in diameter, its solid contents were 943 feet 6 lines cubic, and its power of ascension was found equal to 35 lb.

The 27th of August 1783 having been fixed on for the exhibition of this experiment, the balloon was conveyed, in the preceding night, floating in the air, from a court near the Place des Victoires, where it had been constructed, to the Champ de Mars. The concourse of people, on foot and in carriages, was so immense, that a large body of troops were drawn out to prevent disturbances. At five o'clock in the afternoon, a signal having been given by the firing of a mortar, the cords that confined the globe were cut, and it rose in less than two minutes to a height of near 500 toises. It here entered a cloud, but soon appeared again, ascending to a much greater height; and at last it was lost among other clouds.

In this experiment, too much inflammable air, and even some common air, had been introduced into the globe, which being closed on all sides, left no room for the expansion of this elastic fluid when it should arrive to a more rarefied medium. We find, in fact, that it must have burst in consequence of this expansion; since, after having floated about three quarters of an hour, it fell in a field near Gonesse, a village about five leagues N. N. W. of the Champ de Mars. It must be allowed, that the mere evaporation of the air could not well have been the cause of its descending so soon. Many periodical papers have already entertained the public with ludicrous accounts of the astonishment of the peasants who found it, and of the rough treatment it received at their hands.

It may easily be imagined, that these brilliant successes animated the zeal of all the curious in the metropolis, and that many essays were made to repeat the same experiments upon a smaller scale. A number of secondary attempts accordingly were made; upon which we shall dwell no longer, than only to observe, that they succeeded with globes made of gold-beater's skin, and only 12 inches in diameter; which being thought the least that could be made to ascend, considering that the proportionate weight of the materials increase as the bulk is diminished, were called *mini-*

models.

M. Montgolfier junior having arrived at Paris a few days before the experiment at the Champ de Mars, was desired by the Royal Academy of Sciences to repeat the experiment of Annonay. He accordingly constructed, in a garden in the Faubourg of St Germain, a balloon of an elliptical form, 70 feet high, and 40 feet in diameter. It was lined both inside and outside with paper. Its power of ascension was found upon calculation to be about 1250 lb. It was filled in ten minutes, by the burning of 50 lb. of straw and 10 lb. of chopped wool. It was loaded with a weight of 500 lb. and ascended, fastened to ropes, on the 12th of September, in the presence of the deputies of the

Air.

Royal Academy. But it proving a very rainy day, the whole apparatus was so essentially damaged, that it was not thought proper to set it loose.

We come now to the experiment made on the 10th of September, in the presence of the king and queen, the court, and all the Parisians who could procure a conveyance to Versailles. This balloon was 57 feet high, and 41 in diameter. Its power of ascension, allowing for a wicker cage, containing a sheep, a cock, and a duck, which was suspended to it, was equal to 696 lb. As only four days had been allowed for the making this machine, it could not therefore be lined with paper. M. M. had predicted, that it would remain in the air about twenty minutes, and with a moderate wind might float to a distance of about 2000 toises. But, beside some imperfection in the construction, owing to the great hurry in which it had been made, a sudden gust of wind, while it was inflating, made two rents seven feet long near the top, which could not but in some measure prevent the promised effect. It swelled, however, in eleven minutes sufficiently to raise it about 240 toises; it floated to the distance of nearly 1700 toises; and after having been in the air about eight minutes, it subsided gradually in the wood of Vaucresson. The animals in the cage were safely landed. The sheep was found feeding; the cock had received some hurt on one of his wings, probably from a kick of the sheep; the duck was perfectly well.

M. Montgolfier determined now to repeat the experiment under more favourable circumstances, and more at his leisure. He therefore made a new balloon in a garden in the Fauxbourg St Antoine, which measured 70 feet in height and 46 feet in diameter. A gallery of wicker was contrived round the aperture at the bottom; under which an iron grate or brasier was suspended, and port-holes opened on the inside of the gallery towards the aperture, through which any person *cui robur et æs triplex circa pectus fuerit*, who might venture to ascend, might feed the fire on the grate, and thus keep up the vapour, smoke, or, as we rather apprehend, the *dilatation of the air*, in this vast cavity.

On the 15th of October, M. Pilatre de Rozier, no doubt the most intrepid philosopher of the age, placed himself in the gallery, ascended about 80 feet from the ground, and there kept the balloon afloat for some time, by repeatedly throwing straw and wool upon the fire. In this experiment it was found, that the descent of a globe (provided no extraordinary accident happened to it) must necessarily be gradual; and that it will always light softly upon the ground, since, in fact, in every part of its descent, it enters a denser medium; whence its velocity in falling will rather be retarded than accelerated. On the 19th of October, M. P. Rozier ascended a second time about 250 feet. After continuing stationary about eight minutes, a gust of wind carried the balloon among some trees, where it entangled itself so as to endanger its being torn to pieces: but on M. R. throwing some fresh straw upon the fire, it immediately reascended, amid the loud acclamations of a vast multitude of people, who little expected to see so sudden a recovery. The balloon was then hauled down, and M. Giron de Ville placed himself in the gallery opposite to M. R.

Air.

They were once more let up; and for some time hovered over Paris, in the sight of all its inhabitants, at the height of 324 feet.

Matters seemed now ripe for a *free aerial navigation*. A smoke balloon, very similar to the one last described, was prepared to go off at La Muette, a royal palace in the Bois de Boulogne, where, we are informed, the king's children now usually reside. All things being ready, on the 21st of November M. Pilatre de Rozier took his post in the gallery, and the Marquis d'Arlandes, a major of infantry, placed himself on the opposite side of this gallery, as a counterpoise to preserve the equilibrium of the machine. After repairing some damage done to the balloon in a first essay, it was, at 54 minutes after one, absolutely abandoned to the element; and it ascended with great rapidity.

When these bold adventurers were about 250 feet in the air, they waved their hats to the astonished multitude; but they soon rose too high to be distinguished, and are thought to have soared to an elevation of about 3000 feet. The history of this navigation is, in fact, the history of the alarms of the Marquis d'Arlandes. When he found himself so high that he could no longer distinguish the objects upon earth, he thought both his ambition and his curiosity sufficiently gratified, and desired his companion to cease laying straw upon the fire, that they might descend. M. P. de Rozier, however, deaf to these remonstrances, continued his operations, and the Marquis continued murmuring. At length, being at the highest elevation above mentioned, the latter perceived some holes burst in the sides of the balloon, and likewise heard some cracks near the top of the machine, which seemed to menace instant destruction. He then became outrageous; quickly clapped wet sponges to the burning holes; and vowed, that if his companion would now descend, he would take upon himself the whole blame of having thus shortened their navigation. M. Rozier at length listened to his urgent solicitations: but on approaching the earth, they found that they were descending immediately over the Seine; and fearing lest they might be carried away by the current of air that generally attends streams of water, the Marquis was glad to assist in throwing fresh straw upon the fire; and thus they rose again to a considerable height. On their next approach to the earth, the Marquis seeing the danger they were in of being spitted on the weather-cock of the Invalids, hastily threw a fresh bundle of straw upon the fire, and even spread it, in order to raise a greater blaze. This carried them over a great part of Paris, where they took care to clear all the steeples, &c. and passing the Boulevard, they landed safely in a field near Bicêtre, without having experienced the least real inconvenience. The distance they went was between 4 and 5000 toises. They were in the air about 25 minutes. The collective weight of the whole apparatus, including that of the two travellers, was between 16 and 1700 lb. and when they landed, they had two thirds of their combustibles still left in store.

A more remarkable experiment than any of these hitherto mentioned, was made by Messrs Charles and Robert. The globe prepared for this expedition was made like that of the Champ de Mars, of gores of silk,

Air. silk, alternately red and white, and glazed with some sort of gum. It was spherical, and measured 26 feet in diameter. It was filled with inflammable air; the making of which alone cost 5000 livres. The expence of the whole apparatus amounted to no less than 10,000 livres. A net was spread over the upper hemisphere, which supported a loop that surrounded the middle. To this hoop was suspended, by means of several cords, a boat, that swung at a small distance below the bottom of the globe, and which was so finely ornamented, as to deceive, in this respect, the name they gave it at Paris of a Triumphant Car. In order to prevent the bursting of the globe in a rarefied medium, an opening had been left, with a valve to it, which gave vent to the interior air, but suffered none of the exterior to enter. A long silken pipe or gut proceeded from this aperture; the farther end of which one of the navigators held in his hand, and thereby obtained a considerable command over the inflammable air. The car was ballasted with sand-bags. By these means they hoped, and in fact they succeeded, to guide themselves in point of elevation; for by letting some of the air escape, they naturally descended; and on discharging some of their ballast, they were sure to ascend.

The 1st of December 1783 was fixed upon for this pompous display. Two hundred thousand people assembled in and near the garden of the Thuilleries. The apparatus stood on a scaffolding raised for the purpose, in the middle of a piece of water, to prevent its being approached by the multitude. Upon this it rested, merely by the weight of the ballast in the car. The friends of the navigators had stored it with plenty of provision and clothing; beside which, proper instruments were also embarked. A small balloon, which had been prepared for the purpose, was offered to M. Montgolfier, who, at the request of M. Charles, cut the string by which it was held, and, by this allegory, tacitly received the tributary homage due to him and his brother as the authors of the invention.

At forty minutes past one, Messrs Charles and Robert ascended the Car. They threw out 19 lb. of ballast, and instantly rose, with an accelerated velocity, to the height of about 300 toises. No acclamation, no sound was heard; for the multitude stood silent with fear and amazement. The navigators, however, gave signals of their security, by frequently waving two pennants; and M. Charles apprised his friends below that they were easy and happy, by a note he threw down among the crowd. After continuing a short time stationary, they perceived themselves moving nearly horizontally, in the direction of N. N. W. Finding that some of the inflammable air evaporated, they discharged some ballast; and soon after observing that the heat of the sun dilated the inflammable air, they suffered some of it to escape; and thus they kept pretty nearly in the same level. In this manner they floated twice across the Seine; and over many towns and villages, the surprise of whose inhabitants can more easily be conceived than described. About 56 minutes after their departure, they found themselves out of sight of Paris. They then descended so low as to skim along the surface of the ground, and conversed with several labourers in the fields. Seeing a hill before them, they cast some of their superfluous

clothing out of the car, and thus cleared the eminence. They now made a comfortable meal. Finding themselves near the Isle d'Adam, where the prince of Conti has a palace, they again approached the ground, inquired after the prince, and were told that he was at Paris. At 45 minutes after three, they found themselves over Nefle, a small town about nine leagues from Paris. And there, after sliding a little way along the surface of the ground, they alighted gently, and without the least shock or concussion, in a field.

Of a great number of those who had galloped after the balloon from the Thuilleries, only the dukes de Chartres and Fitz-James, and Mr Farrer an English gentleman, who had relays posted in the direction of the wind, arrived a few minutes after the landing. The others either lamed or killed their horses, or grew tired of the pursuit. After the warmest congratulations, an affidavit was drawn up, and signed by all the parties present.

Mr Charles now declared his intention to reascend alone; but to this the duke de Chartres consented, only on condition that he would return in half an hour. M. Robert alighted; and by the diminution of his weight, the machine acquired a power of ascension equal to about 100 lb.

Mr Charles's account of this second ascent we shall give in his own words: "Thirty peasants held down the machine. I asked for some earth to ballast it, having not above four or five pounds left. A spade was not at hand, nor were there any stones in the meadow, where the machine had alighted. The sun was near setting. I made a hasty calculation of the time requisite for the alteration of weight, and gave a signal for the peasants to quit their hold. I sprang up like a bird. In 20 minutes I was 1500 toises high, out of sight of all terrestrial objects. I had taken the necessary precautions against the explosion of the globe, and prepared to make the observations which I promised myself. In order to observe the barometer and thermometer placed at the ends of the chariot, without altering the centre of gravity, I kneeled down in the middle, stretching forwards my body and one leg, holding my watch and paper in the left, and my pen and the string of the valve in my right hand, waiting for the event. The globe, which at my first setting out was rather flaccid, swelled insensibly. The air escaped in great quantities at the valve. I drew the valve from time to time to give it two vents; and I continued to ascend, still losing air, which issued out hissing, and became visible, like a warm vapour in a cold atmosphere. The reason of this phenomenon is obvious. On earth the thermometer was seven degrees above the freezing point; after 10 minutes ascent, it was five degrees below. The inflammable air had not time to recover the equilibrium of its temperature. Its elastic equilibrium being quicker than that of the heat, there must escape a greater quantity than that which the external dilatation of the air could determine by its least pressure. For myself, though exposed to the open air I passed in 10 minutes from the warmth of spring to the cold of winter, I felt at first nothing disagreeable in the sudden change. When the barometer ceased to rise, I marked exactly 18 inches 10 lines; the mercury suffering no sensible oscillation.

cillation. From this height I deduce an elevation of 1524 toises, or thereabouts, till I can be more exact in my calculation. In a few minutes more my fingers were benumbed by the cold, so that I could not hold my pen. I was now stationary, and moved only in an horizontal direction. I rose up in the middle of the chariot, to contemplate the scene around me. At my setting out, the sun was set on the vallies; but he soon rose for me alone, who was the only luminous body in the horizon, and all the rest of nature in the shade. The sun himself presently disappeared; and I had the pleasure of seeing him set twice in the same day. I beheld, for a few seconds, the circumambient air and vapours rising from the vallies and rivers. The clouds seemed to rise from the earth, and collect upon one another, still preserving their usual form, only their colour was grey and monotonous from the want of light in the atmosphere. The moon alone enlightened them, and showed me that I was tacking about twice; and I observed certain currents that brought me back again. I had several sensible deviations, and observed with surprise the effects of the wind, and saw the streamers of my banners point upwards. This phenomenon was not the effect of the ascent or descent; for I then moved horizontally. At that instant I conceived, perhaps a little too hastily, the idea of being able to steer one's own course. In the midst of my transports, I felt a violent pain in my right ear and jaw, which I ascribed to the dilatation of the air in the cellular construction of these organs, as much as to that of the external air. I immediately put on a woollen cap; yet the pain did not go off but as I gradually descended. For seven or eight minutes I had ceased to ascend; the condensation of the inflammable air rather made me descend. I now recollected my promise to return in half an hour; and, pulling the upper valve, I came down. The globe was now so much emptied, that it appeared only an half globe. When I was between 20 and 30 toises from the earth, I threw out hastily two or three pounds of ballast, and became for a moment stationary, till I descended gently on the field, above a league from the place whence I set out. The frequent deviations and turnings make me imagine that this voyage was about three leagues; and I was gone about 35 minutes."

These successful attempts soon produced the emulation of others. M. Montgolfier, whose method had been so successfully tried by M. Pilatre de Rosier, undertook the construction of a balloon, upon his own principles, much larger than any that had hitherto appeared; and it was given out by his friends, that with this machine he intended to set out from Lyons with a quantity of goods, either for Paris or Marseilles, as the wind should serve. This balloon was composed of double canvas, with three layers of paper between the folds; but, at the desire of M. Rosier, the upper part was changed for a simple cotton cloth. The balloon was 100 feet in diameter transversely, and 126 high, and weighed in all about 8000 pounds. The departure was announced for the 10th of January last; but when the attempt was then made, the globe swelled only partially, and could not be raised. Several other attempts were made on succeeding days, but with equally bad success; and in one of these unsuccessful attempts, part of the canvas was burnt. This damage,

however, was soon repaired; and on the 19th of January the projectors were ready for another trial, when the globe filled in 17 minutes. Seven persons embarked in the machine annexed to it, and ascended amidst the acclamations of 100,000 spectators. The globe first took a N.W. direction, but soon after took to the S. E. It had not floated fifteen, or according to some accounts five minutes, when it descended with a velocity that alarmed the spectators, and alighted in a field not far from the place whence it was set off.

In the next experiment we have to describe, an apparatus was to be applied to a balloon filled with inflammable air, for steering it both horizontally and vertically, and even against a current of air. M. Blanchard of Paris had some years ago announced that he was preparing wings, with which he meant soon to take a flight. The late discovery seemed to hasten the execution of his project. His globe is said to have been only 14 feet 2 inches in diameter: but this must certainly be a mistake; for the weight of air contained in such a globe cannot be supposed equal to that of two people, even of the smallest dimensions, with all their necessary apparatus. Be this as it will, a globe was prepared, which actually was sufficient to raise the necessary weight. To this globe was suspended a car; between the car and the globe was fixed an umbrella 12 feet in diameter, the intention of which was to break the fall in case of any accident: hence it was called *parachute*. To the car were adapted four wings, two on each side, and behind a rudder, all made of taffety dilated by means of whalebone ribs. All this was to be worked by a machinery of M. Blanchard's invention. He was to ascend himself for the purpose of navigating the machine; and Dom. Pech, a Benedictine, was also to ascend for the purpose of making various aerological observations and experiments. Every thing was ready on the 2d of March, in the Champ de Mars. A party of M. Blanchard's friends had assembled at a country-house where he had promised to meet them through the air. The navigators were embarked, and ready to soar, when a young man, a pupil of the *ecole militaire*, suddenly rushed through the crowd, threw himself into the car, and insisted on sharing in the expedition. A scuffle ensued, in which Blanchard was wounded in the hand, the parachute and wings destroyed, and the purpose of the experiment entirely defeated. This madman was at last overpowered, and the two adventurers determined to take a chance flight. They rose accordingly; but their power of ascension was not sufficient to carry them to any height, for which reason they soon landed. Dom. Pech alighted, and Blanchard instantly ascended with great rapidity. The wind being east, he was carried to the westward. The account he gives of his navigation is, that he rose about 2000 toises from the ground; that he found himself at times stationary in a perfect calm, during which the heat of the sun was scorching; that he at different times felt currents of wind in different directions, in some of which the cold was intense; that during these cold intervals he felt an almost unconquerable desire to sleep; that clouds collected under his feet; and that it appeared to him that he was at different times carried towards different parts of the compass. He continued in the air one hour and a quarter; after which

he landed safely near Jev, about five miles from the spot whence he ascended.

These are the most remarkable experiments that have yet been made with respect to this new and extraordinary navigation. The principles on which it is accomplished are those of common hydrostatics; but though the specific lightness of inflammable air easily shows why globes filled with it should rise, the principle on which Montgolfier's balloons ascend seem not to be so generally understood. In an original paper, said to be written by a foreign gentleman of great learning, (Appendix to Monthly Review, vol. lxi.), we find the following reasoning on the subject: "The ingredients used for inflating the machine that was let off at Versailles, consisted of 50 pounds of straw and 5 pounds of wool: and, in a work published by M. Faujas de St Fond on the subject, we are informed, that the gas which inflated the bag was produced by burning these ingredients. Now, in as far as simple combustion is here concerned, the experiments of Dr Priestley, since repeated in a thousand different ways, plainly evince, that the effect of combustion is indeed at first to produce a very light aeriform fluid, viz. inflammable air; but that this air, meeting immediately with atmospheric air, takes fire by its union with the dephlogisticated air; and that the residuum of this, being thus mixed with fixed air, does thereby become specifically heavier than it was before. Thus all that modern chemistry hath hitherto taught us concerning combustion, can point out nothing to us as the immediate result of M. Montgolfier's operation, but a mass of air specifically heavier than common atmospheric air, mixed for an instant with some fuliginous vapours which collect into foot on the sides of the bag, and some aqueous vapours, which likewise condense on those sides and become water. It is impossible therefore to discover *a priori*, in the process of M. Montgolfier, the formation of any gas, or of any aeriform fluid, which in its nature can be specifically lighter than atmospheric air; but, on the contrary, we perceive in his operation the cause of some augmentation in the specific weight of the atmospheric air produced by the combustion.

"These arguments *a priori* are so strongly corroborated by the fact, that no doubt can well be entertained concerning their validity. It appears, that the solid contents of the machine let off at Versailles measured 37,500 cubic feet; that the weight of the common air that is displaced, was 3102 pounds; and as the gas of M. Montgolfier was thought to be about one half lighter than common air, it is there said that this gas weighed only 1596 pounds. Weighed only!—But was it considered, that this gas must have been the produce of no more than 50 pounds of straw and 5 pounds of wool? Is it likely that substances weighing in all 55 pounds, should yield 1596 pounds of air? Is it not surprising that this philosophical paradox should have hitherto escaped unnoticed?

"But let us attend to a particular circumstance mentioned in the account of the experiment, and we shall perhaps find the true cause of the ascension of the machine. The manner in which this large bag was filled, is said to have been by piling it upon a circular stage, and contracting it as much as possible, that very little common air might remain in it. Its orifice was

spread over an aperture in the middle of the stage, and straw was burnt under it. The effect of this operation is thus described: "As soon as the machine began to swell, a rapid current of air immediately took place, which coming from without, rushed into the machine with such force, that before the necessary precautions could be taken, the cloth, which was spread upon the stage and round the fire, in the form of a cylindrical funnel, was agitated with great violence." This account itself clearly points out the cause that swelled and buoyed up the machine: it was filled with common air dilated by heat, in the same manner as if the current of air that passes up a chimney were collected in a large empty bag; which being let loose, would certainly rise and float in the air, until the warm air within, losing its heat, be reduced to the temperature of the surrounding air.

"The sanguine hopes that are entertained of the useful application of this discovery may be gathered from a table, in which the dimensions a machine must have to enable it to raise a certain weight, are set forth upon elaborate calculations. These calculations are founded on the principles, That the air produced by M. Montgolfier is one-half lighter than common atmospheric air, and that the weight of the bag is at the rate of two ounces for each square foot. A formula is hence deduced, in which the proportion between the solid contents and the surface of the sphere are the only elements.

"We must here observe, that if, as appears to us very probable, it be merely the heat that diminishes the weight of air in the experiment, the diminution of one-half seems to be greatly exaggerated. It follows from the observations made by M. de Luc on the dilatation of air by the heat of the atmosphere, that if a certain quantity of air passes from the temperature of 32° of Fahrenheit to that of boiling water, that is, 212°, the original bulk of that quantity will be increased $\frac{7}{11}$ parts of the whole; this therefore is the effect of 180° of Fahrenheit. That a given quantity of air may become one-half lighter, its bulk must be doubled; whence we infer, that a mass of air whose bulk is 500, in order to acquire a bulk of 1000, must increase in heat $\frac{180 \times 500}{186} = 484^\circ$. Now, it is by no

means probable, that the air contained in the machine of M. Montgolfier had ever acquired so considerable a degree of heat. This estimate, therefore, of a specific gravity, one-half less than that of the atmospheric air, manifestly requires to be farther investigated.

"Some inductions on this head may be derived from the circumstances of the experiment made at Versailles. According to the computation of M. Faujas, the weight of the lower air displaced by the inflated machine was 3102 lb. According to the observation of M. Gentil, made at the Royal Observatory, the machine must have ascended 240 toises. By an estimate, as nearly approaching to truth as possible (according to the rules of the measurement of heights by the barometer), of the density of the air at the elevation at which the globe ceased to ascend, this density must have been $\frac{1}{3}$ less than that of the place whence it first rose. Thus, at that elevation, the weight of the air displaced by the machine was only 3015 lb. The machine, together with the air contained in it, weighed

weighed therefore likewise 3015 lb. since it there ceased to rise. But of this total weight 900 lb. was the weight of the bag and its appendages; there remains therefore 2115 lb. for the air. But the air displaced by the machine near the ground weighed 3192 lb. The density therefore of the air contained in the machine, was to that of the air near the ground nearly as 2 to 3, instead of the supposed proportion of 1 to 2. And the excess of its heat above that of the outward air, altho' considerable, is thus found to have been one-half less than that above stated, namely,

$$\frac{180 \times 250}{186} = 243^\circ.$$

"This heat, it seems, may be much less still, and yet carry the machine very high, if such intrepid men as M. Pilatre de Rozier and the marquis d'Arlandes will ascend with it, and keep up the fire at its aperture. For, in fact, as the machine rises, it will undoubtedly, if the same degree of heat be constantly kept up in its cavity, continually emit part of the air it contains. Thus, as soon as the heat of the internal air shall be sufficient to raise the machine from the ground, it must continue to rise without any further increase of that heat, and consequently without there being much more difference between the temperature of the interior and exterior air, than what is necessary to compensate for the weight of the bag and its appendages.

"But a second consideration, that appears to us materially to affect the table above-mentioned, (in which, on the supposition of a constant given specific gravity, nothing is considered but the proportion between the solid contents of the bag and its weight), is, that it can only be applicable to a real gas, and by no means to an air dilated by heat. For the effects of fire of a given intensity in heating its surrounding air, are in the inverse ratio of the squares of the distances: whence it appears that the fire must be increased, not in the simple ratio of the solid contents, but in a much greater one; which it will be very difficult to determine, since there are many other considerations that are to be taken into the computations. Every machine, of whatever kind and of whatever dimensions, may no doubt be inflated by conveying into its cavity the current of air produced by the flame; but this would only be a manner of inflating it similar to that which would be produced by opening the bag to the wind. Now this current of air, thus directed by the flame, would preserve but a small degree of dilatation; and a machine of so immense a size as that for which a subscription is said to be now open at Paris, will probably raise but a small weight, and certainly disappoint the expectations of those who have undertaken to construct it.

"If a farther proof were required, that the balloons of Messrs Montgolfier rise only by the rarefaction of the interior air, we should find it in the account given of the descent of that which was launched at Versailles. "Two game-keepers, who were at about ten yards distance from the place where it subsided, assures us," says M. Faujas, "that it came down remarkably slow, gradually contracting itself as it came nearer the ground." Had this balloon been filled with gas lighter than the atmospheric air, it would not have been thus contracted in its descent: nothing but a change of air could have weighed it down; and in a balloon open at the bottom, this change

would have happened by the entrance of a heavier air, which would have driven the lighter air upwards, and forced it out through the rents in the bag, without suffering it to collapse. But a mass of air dilated by heat, contracts on cooling; and the bag, in that case, being compressed by the outward air, will naturally collapse, or be contracted in its dimensions."

In the Review for March 1784, we find the same kind of reasoning continued with regard to the great balloon at Lyons. "Thus much (says the author of the paper) appears certain, that the success was by no means adequate to the sanguine hopes of the projectors; and indeed, if we recollect how rapidly the effect of fire decreases in proportion to the increase of the distances, and that, in this instance, assuming the effect of the fire at the distance of one foot to be as unit, it could at the top of the balloon, when distended, be no more than $\frac{1}{17776}$ of that unit, we shall not be surprised at the difficulties that occurred, nor at the sudden descent after the globe had reached a cold and rarefied stratum of the atmosphere (even though there had been no rent), in which the necessary dilatation of the internal air would have required a fire much more intense than would have been compatible with the safety of the apparatus."

On reading these observations it immediately occurs, that no fair argument can be drawn from the expansibility of common air to that of air which had passed through fire. The latter contains a great deal of fixed and phlogisticated air, along, no doubt, with some inflammable air which escapes during combustion; perhaps not without a mixture of some kinds of acid, as well as alkaline air, rendered incapable of union by their being so much enveloped with others. Besides all these, there must undoubtedly be also a very great quantity of phlogistic and aqueous vapours, the precise specific gravity of which is altogether unknown. We are not, however, to judge merely from the specific gravities: the degree of expansion to which each of these are subject by the same degree of heat must be taken into consideration; and this makes the calculation *a priori* of the force by which any balloon will ascend, very difficult, if not impossible. To understand this in some measure, however, let us compare the different powers of ascension of one cubic foot of fixed air with a cubic foot of common air, when both are heated to the degree of 212 of Fahrenheit, or to the boiling-point of water. With regard to the common air, it has been determined, that by the heat of boiling-water it is expanded one-third of its bulk. A cubic foot of this element (supposing it 800 times lighter than water, and that a cubic foot of water weighs 1000 ounces or 62½ pounds) will weigh an ounce and a quarter, or 600 grains. By the third part of this weight, therefore, or 200 grains, the cubic foot of rarefied air will rise; and if we could form any vessel to contain it which would weigh less than 200 grains, such vessel would arise along with it. The specific gravity of fixed air is to that of atmospheric air, as 220 to 152, and must therefore weigh $868\frac{8}{17}$ grains. But the expansibility of fixed air is to that of common air, as 220 to 132. By the heat of boiling-water, therefore, a cubic foot of fixed air must lose 333 grains of its weight, which would reduce it to nearly 535 grains; and therefore a cubic foot even of this air, though so

much

Air. much heavier than common atmospheric air, would have a power of ascension by means of the heat of boiling-water, almost equal to 65 grains.

Phlogificated air is to common air in specific gravity, as 140 to 152; in expansibility, as 165 to 132: a cubic foot of it, therefore, will weigh only $552\frac{1}{2}$ grains. By a boiling heat it would lose, according to the above-mentioned proportion, 250 grains. A cubic foot of phlogificated air, then, heated to the degree of boiling-water, would weigh only between 202 and 203 grains, and consequently would have an ascensive power equivalent to 397 grains.

With regard to the other kinds of air which are lighter than phlogificated air, the case is still more evident. However, supposing even the balloon to be filled by means of the fuel with equal quantities of fixed and phlogificated air, it is plain that this mixture, when exposed to the heat of boiling-water, must have a considerably greater power of ascension than common atmospheric air; for the cubic foot of fixed air would have an ascensive power of 65, and the phlogificated air of 397, which added together make 462; while two cubic feet of common air, heated to the same degree, would have only an ascensive power of 400.—It is impossible to ascertain the proportions of the different kinds of air which compose the elastic fluid issuing from burning fuel, but it is easy to see that they cannot be in the proportions assumed above; for the phlogificated air is certainly in the greatest quantity; and hence our author's calculations must be vastly erroneous. The error, however, does not lie altogether here, but likewise in supposing heat to decrease when confined in a close place in the same proportion as in the open air. Without entering into any investigation of the causes, it is a well-known fact that heat *ascends* and *accumulates* in the upper part of any close place, as evidently as water *descends* and *is accumulated* in the lower part of any vessel into which it is poured. In any balloon, therefore, which is raised and kept up by fire, the upper part will constantly be hotter than the lower; excepting, indeed, those places which are immediately adjoining to the fire. The fire, therefore, is by no means to be increased in proportion to the cubical contents of the balloons, otherwise it would be impossible to preserve them from destruction. The following experiments were made with a view to determine these matters, as far as they can well be determined in miniature.

Three different parallelpipeds were prepared, by pasting writing paper over slight wooden frames. Externally the smallest measured 6 inches square, and 12 inches in height; the under-part being left quite open. Its cubical contents thus were 432 inches, or the fourth-part of a cubic foot; but by reason of the space occupied by the wood-work, it could not be estimated at more than 417 inches. The second measured exactly a cubic foot; and, deducting for the space occupied by the wood, measured 1710 inches. The third was one foot square, and two feet in height, and contained two cubical feet; and, deducting the wood as before, measured 3430 inches. The weight of air, therefore, contained in the least, was nearly $144\frac{1}{2}$ grains; in the second, $593\frac{1}{5}$; and in the third, $1186\frac{1}{5}$. The first being suspended in a balance and exactly counterpoised, a lighted candle was held under the open part

at bottom. The machine instantly rose, and required 30 grains to bring it again into balance. A thermometer held within the cavity with the bulb upwards, stood, when taken out, at 118°. The second being now suspended in like manner, and exactly counterpoised, required 75 grains to bring it into balance; the thermometer standing at 106 within its cavity. The third, with the same candle, and treated in every respect in a similar manner, required 90 grains to bring it back to an equilibrium; the thermometer standing at 88.—On using a stronger heat, the first required 75, the second 255, and the third 405 grains to restore the equilibrium; the thermometer standing in the two first at 170, and in the last at 135.

From these experiments, it is evident, that the rarefaction of air which passes through fire, cannot in any manner of way be calculated from the rarefaction of common air by heat alone. In the first set of experiments, 417 cubic inches of air were rarefied one-fifth by the flame of a small candle; 1710 inches, by the same rule, were rarefied about an eighth; and 3430 inches were rarefied one-thirteenth. But in the common mode of computation, if the flame of the candle had rarefied the first quantity of air one-fifth, it ought to have rarefied the second, which was four times greater, only one-twentieth, and the third only one-fortieth part. Nay, according to the assertion above-quoted, that “the fire must be increased, not only in proportion to the cubical contents, but in a much greater proportion,” the effects of the candle ought to have been still much less than we have calculated them. But this is not all. The room in which these experiments were made was warm, and the thermometer stood at 70°. By an expansion of 48° only, one-fifth part was rarefied; but if 180° of Fahrenheit give very little more than one-third of rarefaction, 48 degrees ought to have given scarce a fourth-part of that third, or a twelfth part instead of a third. In like manner, when the strong heat was used, the weight raised by its means indicated a rarefaction of more than one-half, though by the thermometer it ought not to have been one-third.

It now remains only to give some instructions for making balloons. 1. For those who intend only to construct a small balloon merely to enjoy the sight of its ascent in the air, inflammable gas will be found most eligible. Indeed it is almost the only kind that can be used; for the other kinds are so little inferior in specific gravity to the common atmosphere, that it will require a very capacious bag to rise when filled with them. The lightest materials are to be procured; and it is a matter of no small difficulty to determine what these materials are. Thin silk covered with elastic gum dissolved in æther has been found to answer the purpose of confining inflammable air more perfectly than any other thing; but as this material is excessively dear, a varnish made of linseed oil has been tried, and found to answer tolerably well. Indeed, instead of silk, thin paper varnished may be used: for as neither silk nor paper will contain inflammable air by themselves, it is plain, that the only use of these materials is to support the varnish; and while this can be done, it is no matter by what means. In fact, the widest gauze may be covered with isinglass or gums properly dissolved,

Air.

solved, in such a manner as to be capable of containing inflammable air; and the thinner and lighter the materials are, the less may be the diameter of the intended balloon.

With regard to the form, that of a sphere is most proper, as a body of this kind meets with less resistance in passing through the air than any other. A small aperture is always to be left, for the purpose of admitting the inflammable air with which the balloon is to be filled. From this aperture a gut or pipe ought to proceed, of such a length as to admit of being easily and closely tied when the vessel in which the inflammable air was produced shall be removed.

The balloon being fully prepared, its sides are to be squeezed together as completely as possible; but at the same time very gently, lest the varnish should be cracked. This is done to get out of it all the common air which it originally contained; for the less of this that remains in it, the more easily will the balloon ascend, and the greater weight it will be able to carry up. To fill it with inflammable air, a sufficient quantity of vitriolic acid and filings of iron or zinc must be procured. For a globe of three feet diameter the following proportions have been recommended; 40 ounces of vitriolic acid, 90 of iron-filings, and 450 of water. The most proper vessel for mixing these ingredients is a copper-still, perforated at top for the convenience of pouring in more acid or water as shall be necessary. This metal is to be chosen in preference to any other, on account of its not being easily affected by fire, and being likewise insoluble in diluted vitriolic acid. The still is to be fitted with a refrigeratory and worm, in order to condense any aqueous vapour that may arise along with the air. This condensed vapour must be received into a small vessel exactly fitted to the worm; and into the upper part of which must be closely inserted a tube of tin or some other solid material capable of conducting the air, without losing it, into the balloon. The acid diluted with the water is first to be put into the still, and the iron gradually added through the hole in the top. An effervescence will immediately ensue, and the balloon will swell considerably; but as the dilatation advances, the resistance of the external air rather increases at the same time that the propelling force of the inflammable air is lessened. Fire must therefore be applied to the still; which will soon expel all the inflammable air, and would even burst the balloon if long continued. Unless a valve is applied to let out part of the inflammable air when it ascends into the higher regions, it will be improper to fill the balloon very full; because of the danger of bursting in a more rarefied air. A method of making balloons ascend to a prodigious height, would be to have a valve opening outwards, and confined by a spring, the elasticity of which could be overcome by the expansion of the air, without bursting the globe. This valve ought to open into another flaccid balloon, by which means the air that escaped from the former would not be lost, but dilate the second; so that both would have the same propensity to ascend that the single one had. On their entrance into a region where the air was still more rare, both would be diffused; and thus by connecting three, four, or more bags with one another, it seems practicable in theory to raise them to any height whatever.

Air,
Albians

2. The other kind of balloons, which are raised by means of air passing through fire, seem scarcely proper for experiments except of the higher kind, where some person ascends with them, and regulates their motion by increasing or diminishing the fire by which they are supported. With regard to the construction of these, little can as yet be said, excepting what may be inferred from the experiments of M. Montgolfier and Rosier. The descriptions of these already given sufficiently show the method of constructing *fire balloons*, as they are called. The only remark that can well be made on them at present is, that in these, as well as the others, the whole power of ascension lies on the top; because there the pressure of the atmosphere is considerably less than at bottom; whereas the expansive power of the air within continues the same over the whole. In the great balloon constructed at Lyons, which was 126 feet in height, the difference between the external and internal pressure must have been very great. Every cubic foot of air weighs about an ounce and a quarter. Of consequence, upon every cube of one foot, the air presses with one ounce and a quarter less weight on the upper than on the under part. Nevertheless, if we suppose the cube hollow, and filled with air, the internal air will press upon that which lies below it with a force equal to one ounce and a quarter; of consequence, the cube will neither have any inclination to ascend or descend; but if we lighten the internal air by any given quantity, suppose half an ounce, while we preserve the same elasticity with the external air, it is plain, that the upper and internal part of the cube will be pressed upwards by half an ounce more than it is pressed downward by the external air. Hence it is evident, that the upper part of these machines, instead of being weaker, ought to be stronger than the under parts. This is evident from what happened to the balloon at Lyons. At the height of 126 feet, there must have been a difference of no less than 9 pounds 13 ounces upon every square foot, between the internal and external pressure. From this indeed the weight of the internal column must be deducted; but supposing the air to have been but very little rarefied, the difference must have been immense. In fact, this difference is the very power of ascension itself; and we see that this was sufficient to overcome 8000 pounds weight, for the machine itself, besides that of seven people, whom we cannot well suppose to have weighed less than 1000 pounds. Now, as the diameter of the balloon was 100 feet, we see that the whole pressure rested upon a circle of cotton cloth, whose diameter was 100 feet, and area 7850. The pressure therefore was more than a pound upon every square foot, and how much more we do not know, unless the machine had been perfectly in *equilibrium* with the atmosphere. But this it was not: for it ascended with great velocity; and the power by which this velocity was occasioned, exerted itself upon the upper parts. The consequence was, that the cloth was torn; having been imprudently changed by M. Rosier from double canvas to single cotton.

ALBINUS (Bernhard Siegfried), a celebrated physician and anatomist, was born, of an illustrious family, at Francfort on the Oder in 1697. His father was then professor of the practice of medicine in the university of Francfort; but in the year 1702 he repaired to Ley-

den,

pus,
bugo.

den, being nominated professor of anatomy and surgery in that university. Here his son had an opportunity of studying under the most eminent masters in Europe, who, from the singular abilities which he then displayed, had no difficulty in prognosticating his future eminence. But while he was distinguished in every branch of literature, his attention was particularly turned to anatomy and surgery. His peculiar attachment to these branches of knowledge gained him the intimate friendship of Ruyfch and Rau, who at that time flourished in Leyden; and the latter, so justly celebrated as a lithotomist, is said to have seldom performed a capital operation without inviting him to be present. Having finished his studies at Leyden, he went to Paris, where he attended the lectures of Du Verney, Vaillant, and other celebrated professors. But he had scarce spent a year there, when he was invited by the curators of the university of Leyden, to be a lecturer in anatomy and surgery at that place. Though contrary to his own inclination, he complied with their request, and upon that occasion was created Dr of physic without any examination. Soon after, upon the death of his father, he was appointed to succeed him as professor of anatomy; and upon being admitted into that office on the 9th of November 1721, he delivered an oration, *De vera via ad fabricæ humani corporis cognitionem ducentes*; which was heard with universal approbation. In the capacity of a professor, he not only bestowed the greatest attention upon the instruction of the youth entrusted to his care, but in the improvement of the medical art. With this view, he published many important discoveries of his own; and by elegant editions, turned the attention of physicians to works of merit, which might otherwise have been neglected. By these means his fame was soon extended over Europe; and the societies of London, Peterburgh, and Harlem, cheerfully received him as an associate. In 1745, he was appointed professor of the practice of medicine at Leyden, and was succeeded in the anatomical chair by his brother Frid. Bern. Albinus. He was twice rector of the university, and as often he refused that high honour when it was voluntarily offered him. At length, worn out by long service and intense study, he died on the 9th of September 1770, in the 74th year of his age.

ALBUGO. *Dele* the marginal note.

Some distinguish this disorder by *nubecula*, when its seat is superficial; and *albugo*, when it is deep. Others make the following distinctions, viz. when the speck appears of a shining white, and without pain, it is called a *cicatrice*; when of an opaque whiteness, an *albugo*. Seated superficially, it hath been termed a *speck*; and more deeply, a *dragon*. If an abscess was the cause, its contents hardening between the laminae of the cornea, causes it to project a little; and then it is called a *pearl*.

The causes are various; as inflammation in the eye, abscess in the cornea, erosion, measles, small-pox, wounds, burns, &c.

When deep, the cure is difficult; when the consequence of a wound or ulcer, they are rarely cured; when caused by an imprudent use of vitriolic collyriums, and when they alter the natural shape of the eye, the prognostic is as unfavourable. Those which follow an inflammation, generally disappear spontaneously.

Happening after the small-pox, measles, or other inflammatory causes, the utmost haste should be made to relieve, by bleeding, purging, blistering, diuretics, and an abstemious diet. Avoid cold and astringent collyriums; but the fumes of coffee, or of the decoction of the woods, may be useful. When these specks *Motherby*, are very small, they often ulcerate; but these ulcers *Med. Dis.* are soon healed by the application of the *pulv. rad. irid. paucul. fac. chrysal.* or, as is justly preferred by many, the *agg. sapph.* If the disorder hath been of long standing, the cure is very difficult; however, the following methods may be attempted: expose the diseased part of the eye to the fumes of camphorated spirit of wine directed through a quill: this, by a continued use, may abrade the speck. This method seldom fails to excite some degree of inflammation, by which the cure is effected; though when the inflammation is thus produced, it must be removed by the common methods with all possible speed. To this end, the following have been also applied with some degree of success, viz. the juice ofcelandine, the gall of elcs, or of the pike, or of a partridge, and the oil of box: if these prove too sharp, let them be diluted with water, or with a thin solution of gum dragon: apply any of these once in 24 hours; and half an hour after the application, wash it off with a little brandy and water. The *ag. sapph.* alone sometimes succeeds. When the film is very tough, and the eye not inflamed, common glass finely levigated may be blown upon it through a quill, and repeated once in a day or two.

ALBURNUM, the soft white substance which in trees is found between the liber or inner bark and the wood, and in progress of time acquiring solidity, becomes itself the wood. From its colour and comparative softness, it has been styled by some writers the fat of trees, *adeps arborum*.

The alburnum is found in largest quantities in trees that are vigorous; though in such as languish, or are sickly, there is a greater number of beds. In an oak six inches in diameter, this substance is nearly equal in bulk to the wood. In a trunk of one foot diameter, it is as one to three and a half; of two and a half feet diameter, as one to four and a half, &c. but these proportions vary according to the health and constitution of the trees.—The alburnum is frequently gnawed in pieces by insects which lodge in the substance, and are nourished from it.

ALDER, (*Encycl.*) The bark of the black berry-bearing alder is said to be the most certain purge for the horned cattle in obstinate constipations of the bowels. Gunner says, that horses do not eat the leaves, but that cows sometimes will, and that it greatly increases the quantity of the milk.

ALGÆ, FLAGS; one of the seven families or natural tribes into which the whole vegetable kingdom is divided by Linnaeus, in his *Philosophia Botanica*. They are defined to be plants, whose root, leaf, and stem are all one. Under this description are comprehended all the sea-weeds, and some other aquatic plants. In the sexual system, they constitute the third order of the 24th class *cryptogamia*; in Tournefort, the second genus of the second section, *marines, aut fluviales*, of the 17th class, *asperma vulgo habita*; and the 57th order in Linnaeus's Fragments of a Natural Method. The discoveries made in this part of the vegetable kingdom are

Albugo
Alge.

uncertain, and imperfect; and the attempts, in particular, to arrange flags by the parts of the fructification, have not been attended with great success. Dillenius has arranged this order of plants from their general habit and structure; Michelius from the parts of fructification.—Each has considerable merit.

ALIMENT. Marginal note, for n° 438, &c. read 440—442.

A considerable change has now taken place in the vegetables made use of as food by the ancients, by substituting, instead of what were then used, a number of more bland, agreeable, and nutritive juices. The acorns and nuts of the primitive times have given way to a variety of sweeter farinaceous seeds and roots. To the malvaceous tribe of plants so much used by the Greeks and Romans, hath succeeded the more grateful spinach; and to the blite, the garden orach. The rough borage is supplanted by the acescent sorrel; and asparagus has banished a number of roots recorded by the Roman writers under the name of *bulbs*; but Linnaeus is of opinion, that the parsnip has undeservedly usurped the place of the skirret. The bean of the ancients, improperly so called, being the roots, as well as other parts of the *nymphaea nelumbo*, or Indian water-lily, is superseded by the kidney-bean. The garden rocket, eaten with, and as an antidote against the chilling qualities of the lettuce, is banished by the more agreeable cress and tarragon; the apium by the meliorated celery; the pomponi, and others of the cucurbitaceous tribe, by the melon; and the fumach berries, by the fragrant nutmeg. The silphium, or succus Cyrenaicus, which the Romans purchased from Persia and India at a great price, and is thought by some to have been the asafetida of the present time, is no longer used in preference to the alliaceous tribe.

To turn from the vegetable to some of the animal substitutes, we may mention the carp among fishes, as having excluded a great number held in high estimation among the Romans. The change of oil for butter; of honey for sugar; of mulsa, or liquors made of wine, water, and honey, for the wines of modern times; and that of the ancient zythus for the present improved malt liquors; not to mention also the *calida* of the Roman taverns, analogous to our tea and coffee.

ALKADARII, a sect among the Mahometans, who deny any eternal, fixed, divine decrees, and are asserters of free will. The word is formed from the Arabic *alkadar*, which signifies "decree." The Alkadarii are a branch of Motazalites, and stand opposed to the Algiabarii. See ALGIABARII, (*Encycl.*)

ALKALI, (*Encycl.*) Alkalis comprehend one class of the chemical elements, or component parts or neutral salts, as acids do another. Concerning the origin of alkalis there have been a great number of various conjectures, as well as concerning that of acids; but nothing certain has been, or in all probability will be, discovered. They are distinguished from other bodies of the saline kind by the following properties.

1. They combine with acids more readily than any other known substance, excepting the pure ponderous earth, occasioning an effervescence and heat. 2. When they are in a concrete form, into which they may be easily reduced by evaporation; if exposed to the open air, they attract the moisture from it, though not so strongly as concentrated acids; and generally deliquesce,

that is, become a fluid: But if they are mixed with water all at once, a considerable degree of heat is produced. 3. They generally change the blue and red colour of vegetables to a green; whereas the acids change it to red, or to a stronger red. 4. They have an acid burning taste, which has something of urinous. 5. They partly exhale with water, especially when boiled in open vessels. 6. They may be fused by a moderate heat; and in that state they dissolve all sorts of earths, especially those called *vitrisifiables*; and if the heat is sufficient, they and the earth form a brittle substance called *glass*; and upon this principle common glass is made.

Alkalis are principally distinguished into *fixed* and *volatile*; the former being not so easily dissipated even by a strong fire; for which reason they are commonly employed in making glass, and other compositions. But the volatile alkalis are so easily dissipated, that they may be almost entirely evaporated by a much less degree of heat than that of boiling water. Notwithstanding that various sorts of alkali are enumerated, it is supposed that there is but one alkaline principle in nature, which, by being variously combined with sundry substances, assumes various particular properties. However, an alkali is never found pure in nature, but it is always combined with other substances, from which it must be separated by art, in order to obtain it sufficiently pure. The fixed alkali is obtained either from sea-salt, or from vegetables; hence it is called *fixed mineral alkali* in the first case, and *fixed vegetable alkali* in the second. The volatile alkali is obtained, by means of decomposition and putrefaction, from all animal substances, and may be also obtained by decomposition and other means from some vegetable and a few other matters. Fixed alkali, whether vegetable or mineral, has always the same principal properties; yet they differ from one another in degree, viz. the mineral alkali possesses the alkaline properties in a less degree than the vegetable alkali; for when it is exposed to the open air, it will not attract the moisture from it in such a quantity as to deliquesce; when mixed with water, it will not occasion so much heat as the fixed vegetable alkali, &c.—Its affinity with other substances is exhibited below:

- | | |
|---------------------------|---------------|
| 1. Vitriolic acid, | 8. Oils, |
| 2. Nitrous acid, | 9. Tin, |
| 3. Marine acid, | 10. Lead, |
| 4. Phosphoric acid, | 11. Copper, |
| 5. Acid of sugar, | 12. Gold, and |
| 6. Other vegetable acids, | 13. Water. |
| 7. Sulphur, | |

The fixed vegetable alkali has an affinity with the following substances:

- | | |
|---------------------------|---------------|
| 1. Vitriolic acid, | 8. Oils, |
| 2. Nitrous acid, | 9. Tin, |
| 3. Marine acid, | 10. Lead, |
| 4. Phosphoric acid, | 11. Copper, |
| 5. Acid of sugar, | 12. Gold, and |
| 6. Other vegetable acids, | 13. Water. |
| 7. Sulphur, | |

Alkaline salts are of great use in chemistry, not only because they counteract the action of acids, but also because they are powerful solvents; and, when combined with other substances, communicate to them part of their saline properties. Thus, when they are com-

combined with sulphur, they make a compound called *hepar sulphuris*, or liver of sulphur, which is dissolvable in water, whereas sulphur by itself is not; and when they are combined with oils, form compounds called *saps*, which are dissolvable in water, whereas oil by itself is not. The fixed alkali, more commonly used, by reason of its greatest purity, is that extracted from tartar, which is a substance found adhering to the sides of casks that have contained wine, and is considered as the essential salt of that liquor. This alkali, when it is in a liquid form by its combination with a sufficient quantity of water, is commonly, but improperly, called *oil of tartar*.

Volatile alkali, when first extracted from animal or vegetable substances, is very impure; but by proper methods it may be purified to a great degree; and in that purified state it differs from fixed alkali, principally because it is very volatile: it has a strong penetrating smell, which occasions coughs, suffocation, &c.—The hart's-horn drops commonly used, the smell of which almost every body knows, are a volatile alkali.

ALL-SPICE, PIMENTO, or Jamaica Pepper. See PIMENTO, (*Encycl.*)

ALOE, (*Encycl.*) The *mitre-shaped aloe*, so termed from the figure of its leaves, is a kind of symbolic plant to the Mahometans, especially in Egypt, and in some measure dedicated to the offices of religion; for whoever returns from a pilgrimage to Mecca, hangs it over his street-door, as a token of his having performed that holy journey. The superstitious Egyptians believe, that this plant hinders evil spirits and apparitions from entering the house; and on this account, whoever walks the streets in Cairo, will find it over the doors both of Christians and Jews. From the same plant the Egyptians distil a water, which is sold in the apothecaries shops at Cairo, and recommended in coughs, hysterics, and asthma. An unexperienced French surgeon, says Hasselquist, gave a Coptite, 40 years old, affected with the jaundice, four tea-cups full of the distilled water of this species of aloe, and cured him in four days. This remedy, unknown to our apothecaries, is not difficult to be obtained, as the plant might easily be raised in the warm southern parts of Europe. The Arabians call it *sabbara*.

The under leaves of a species of aloe, termed by Linnaeus *aloe disticha*, are of a dark-green colour, spotted with white, somewhat resembling the colour of soft soap; whence it is sometimes distinguished by the name of *soap-aloe*.

The name of *pearl aloe* is given to a certain species, the leaves of which are closely fludded with white beautiful protuberances.

Of the leaves of the Guinea aloe, mentioned by Mr Adanson in his voyage to Senegal, the negroes make very good ropes, not apt to rot in the water.

Dr Sloane mentions two sorts of aloe; one of which is used for fishing-lines, bow-strings, stockings, and hammocks; the other has leaves which, like those of the wild-pine and banana, hold rain-water, and thereby afford a very necessary refreshment to travellers in hot countries, where there is generally a scarcity of wells and water.

The substance known among druggists and apothecaries by the name of *aloe*, is a thick, or inspissated juice, drawn from the plants by expression or incision. Of this substance there are three sorts, which differ in purity, and, according to most authors, are the produce of the same plant.

The manner of collecting and preparing the juice, is thus explained by J. Bauhin: having cut the herb in pieces, they bruise it, and squeeze out the juice, which they put up into a vessel of a long and round shape, suffering it to stand for the space of 25 days; in the meanwhile they take care to clear off the useless-scum, and throw it away, as also the upper part of the juice, until such time as some difference appears in its colour and consistence. The purer part of this juice being concreted, or hardened, is called *fuccotrine aloe*; the remaining part, being of a dark liver-colour, is called *hepatic aloe*; and from the dregs or settlings, is made that sort called *caballine* or *horse aloe*.

Notwithstanding the contrary opinion of Columna, Bauhin, Ray, and other naturalists, we are now sufficiently certain, that the three kinds of aloe just mentioned, are the juices of three different plants: the fuccotrine, of the *aloe vera* of Miller; the hepatic, of the *aloe vulgaris* of Bauhin, also *Discordis et aliorum* of Sloane, and *aloe barbadensis* of Miller; the caballine, of the *aloe Guineensis caballina, vulgari similis, sed tota maculata*, of Commelin.

The finest or purest is the fuccotrine aloe; so called, says Pomet, either because the substance itself is a concreted juice, or, which is most probable, because the best comes from Socotora, or Zocotra, an island in the streights of Babelmandel. Succotrine aloe, when broken, is transparent; and when powdered, of a fine yellow golden colour, with a bitter taste, and a smell like that of myrrh. From the root and leaves of the West-India, or Barbadoes aloe, is prepared the second sort, called from its colour, which is a dark-red like that of a liver, *hepatic aloe*. This sort, which is coarser than the former, and seldom used in medicine except for horses, is brought up in gourds or calabashes of different sizes and weight. It is of a liver colour, clear, and not very fetid in smell.

The third sort, by much the coarsest, black, hard to break, and frequently adulterated, is called *caballine aloe*; because, like the second sort, it is solely appropriated to the use of horses. This sort is generally sold in the shops for the true hepatic aloe.

The month of March, says Mr Hughes in his Natural History of Barbadoes, is the properest season to make the aloe; which is done in the following manner: Each negro has by him three or four portable tubs, into which the leaves are thrown with their broken ends downwards. These being full of large longitudinal veins, or vessels, yield an easy passage to the juice, which is of a greenish yellow colour, to drip out. The juice being boiled for about five hours in a copper or kettle, the watery particles evaporate, and the remainder comes to a consistency, and thickens as sugar doth when sufficiently boiled. The way to know when it is enough boiled, is to dip a stick in the liquor, and observe whether the aloe, sticking to it when cold, breaks short; if it does, then it is boiled to perfection, and fit to be poured into gourds, calabashes, or other vessels for use.

Alopecia
Amalgama-
tion.

Succotrine aloes, which is the only sort now prescribed in medicine, is seldom or never administered in potion, by reason of its extreme bitterness; but is often given in pills, being in fact the basis of the greatest part of the purgative pills now in use. The Francfort or angelic pill is entirely composed of it. In the city of Goa, as Garcias relates, aloes well bruised and mixed with milk, is prescribed with success, to such as are afflicted with ulcers in the kidneys or bladder, and void purulent urine. The herbs which produce the three medicines just mentioned, are by no means to be confounded with the tree from which is procured the precious, valuable, and rare wood called *wood of aloes*.

ALOPECIA, (*Encycl.*) *Dele* the marginal note.

The term is used among physicians to denote a total falling off of the hair from certain parts, occasioned either by the defect of nutritious juice, or by its vicious quality corroding the roots of it, and leaving the skin rough and colourless.

The word is formed from *αλωπε*, *vulpes*, "a fox;" whose urine, it is said, will occasion baldness; or because it is a disease which is common to that creature.

The alopecia properly differs from *desuvium capilorum*; as in the former certain parts or patches are left entirely bald, whereas in the latter, the hair only grows immoderately thin. It also differs from the ophiasis, as this latter creeps in spies about the head, like the windings of a serpent; whereas the former is not confined to any figure.

The remedies which remove the proximate cause of this malady, are called *μετασυνκριτικά, metasthcrítica*. Here, first, if any corrupt hairs still remain, they are to be drawn out either with tweezers, or by dropacism; or the place must be shaved by a razor. Then the head is to be washed every night at going to bed with a ley, prepared by boiling the ashes of vine branches in red wine. A powder made by reducing hermodactyls to fine flour, is also recommended for the same purpose.

In cases where the baldness is total, a quantity of the finest burdock roots are to be bruised in a marble mortar, and then boiled in white wine until there remains only as much as will cover them. This liquor, carefully strained off, is said to cure baldness, by washing the head every night with some of it warm. A ley made by boiling ashes of vine branches in common water, is also recommended with this intention. A fresh cut onion, rubbed on the part until it be red and itch, is likewise said to cure baldness.

A multitude of such remedies are every where to be found in the works of Valerius de Taranta, Rondeletius, Hollerius, Trincavellius, Cellus, Senertay, and other practical physicians. See *Buxus*, (*Encycl.*)

AMALGAMATION, (*Encycl.*) The proper method of making amalgams is, by first melting the metal with as little heat as possible, and then pouring the quicksilver into it. During this operation part of the metal undergoes a kind of calcination, whence the sur-

face of some amalgams become black and dusky in a very short time. This is effectually prevented by adding a small quantity of tallow or hog's-lard to the mixture whilst hot; which restores the phlogiston lost by the metal, and preserves the mixture always of a metalline splendor. This is especially necessary in making an amalgam with zinc, which is found to excite the electrical power of glass more than any other. It requires at least four parts of zinc to one of mercury.

AMAUROSIS. Marginal note, for 790, read 455.

AMBERGRISSE, (*Encycl.*) In the Philosophical Transactions we meet with an account of the origin of substance, very different from the commonly received one of its being a natural bitumen. This account was communicated to the Society by Paul Dudley, Esq; who had it from an American shipmaster. It is in substance the same with the account given by Doctor Douglas in his Historical and Political Summary of the English Colonies, vol. i. p. 57. "Ambergrise," says he, "is now fully discovered to be some production of the spermaceti whale; for some time it was imagined some peculiar concreted juice lodged in a peculiar cystis, in the same manner as is the castoreum of the beaver or fiber canadensis, and the zibethum of the civet-cat or hyæna, in cystises on both sides in the ani rima. Thus, not long since, some of our Nantucket whalers imagined, that in some (very few and rare) of these male or bull-whales, they had found the gland or cystis in the loins near the spermatic organs: late and more accurate observations seem to declare it to be some part of the ordure, dung, or alvine excrement of the whale. Squid fish, one of the Newfoundland baits for cod, are sometimes in Newfoundland cast ashore in quantities; and as they corrupt and fry in the sun, they become a jelly or substance of an ambergrise smell; therefore, as squid bills are sometimes found in the lumps of ambergrise, it may be inferred, that ambergrise is some of the excrement from squid food, with some singular circumstances or dispositions that procure this quality seldom concurring. Thus the Nantucket whalers, for some years last past, have found no ambergrise in their whales."

In the sixth volume of Goldsmith's Natural History, we find an account somewhat different from the foregoing. He tells us, that it is found in the cachalot or spermaceti whale, in the place where the seminal vessels are usually situated in other animals. It is found in a bag of three or four feet long, in round lumps, from one to 20 pounds weight, floating in a fluid rather thinner than oil, and of a yellowish colour. There are never more seen than four at a time in one of these bags; and that which weighed 20 pounds, and which was the largest ever seen, was found single. These balls of ambergrise are not found in all fishes of this kind, but chiefly in the oldest and strongest. In the 73d volume of Philosophical Transactions, Dr Schewdiner gives an account very similar to the former one.

AMSTER-

Amanreia
Amputa-
tion.

AMSTERDAM ISLAND, (*Encycl.*) said there, by mistake, not to be taken notice of in our later discoveries. It was visited by capt. Cook in his late voyages. Its greatest extent from east to west is about 21 miles, and from north to south about 13. It is broad at the east end, and runs taper towards the west, where it turns, and runs to a point due north. It is about six leagues to the west of Middleburgh. The shore is surrounded by a coral rock, and its most elevated parts are not above six or eight yards above the level of the sea. S. Lat. 21. 11. W. Long. 175. It is wholly laid out in plantations, in which are cultivated some of the richest productions of nature.

Here are bread-fruit, cocoa-nut trees, plantains, bananas, shaddocks, yams, and some other roots; sugar-canes, and a fruit like a nectarine, called by the natives *fighega*. There did not appear an inch of waste ground: the roads occupied no more space than was absolutely necessary: the fences did not take up above four inches each; and even these were not wholly lost, for in many grew some useful trees or plants: it was every where the same, change of place altered not the scene: nature, assisted by a little art, nowhere appeared in more splendor than on this island. Water is not so plentiful here as at the Society-islands; but the chief pointed out a pool of fresh water unasked, to supply the ships with that necessary article. Casuarinas, pandangs, and wild sago-palms, appear here with their various tints of green, and barringtonia as big as the loftiest oaks. The bread-fruit does not, however, thrive here with the same luxuriance as at the Society-islands, the coral rock, which composes the basis of this spot, being much more thinly covered with mould.

Both men and women are of the common size of Europeans, and their colour is that of a lightish copper; they are well-shaped, have regular features, are active, brisk, and lively. They have fine eyes, and in general good teeth, even to an advanced age. The women are the merriest creatures imaginable, and incessant talkers. In general, they appear to be modest; although there was no want of those of a different stamp. Among the natives, who swam about the ship very vociferously, were a considerable number of women, who wanted in the water like amphibious creatures, and were easily persuaded to come on board perfectly naked; but none of them ventured to stay there after sunset, but returned to the shore to pass the night, like the greater part of the inhabitants, under the shade of the wild wood which lined the coast. There they lighted great fires, and were heard conversing almost the whole night. The hair of both sexes in general is black, but especially that of the women; both sexes wear it short, except a single lock on the top of the head, and a small quantity on each side. The men cut or shave their beards quite close, which operation they perform with two shells. The hair of many was observed to be burnt at the ends, and strewed with a white powder, which was found, on examining it, to be lime made of shell or coral, which had corroded or burnt the hair; some made use of a blue powder, and others, both men and women, of an orange-coloured powder made of turmeric.

The dress of both sexes consists of a piece of cloth or matting wrapped round the waist, and hanging

down below the knees. From the waist upwards they are generally naked, and it seems to be a custom to anoint these parts every morning. The practice of tattooing, or puncturing the skin, likewise prevails. The men are tattooed from the middle of the thigh to above the hips; the women have it only on their arms and fingers, and on those parts but very slightly. Their ornaments are amulets, necklaces, and bracelets, the bone, shells, and beads of mother-of-pearl, tortoise-shell, &c. which are worn by men as well as women. The women also wear on their fingers neat rings made of tortoise-shell, and pieces in their ears about the size of a small quill: but here ornaments are not commonly worn, though all have their ears pierced. They have also a curious apron, made of the out-side feathers of the cocoa-nut shell, and composed of a number of small pieces, sewed together in such a manner as to form stars, half-moons, little squares, &c.; it is studded with beads and shells, and covered with red feathers, so as to have a pleasing effect. They make the same kind of cloth, and of the same materials, as at O-Taheitee, though they have not such a variety, nor do they make any so fine; but as they have a method of glazing it, it is more durable, and will resist rain for some time, which the other cloth would not. Their colours are black, brown, yellow, purple, and red; all made from vegetables. They make various sorts of matting, some of a very fine texture, which is generally used for cloathing; and the thick and stronger sort serves to sleep upon, and to make sails for their canoes, &c. Among other useful utensils, they have various sorts of baskets, some made of the same materials as their mats, and others of the twisted fibres of cocoa-nuts. These are not only durable, but beautiful, being generally composed of different colours, and studded with beads made of shells or bones. They have many little nicknacks among them, which show that they neither want taste to design, nor skill to execute, whatever they take in hand. Their fishing implements are much the same as in other islands: here was purchased a fish-net made like our casting-nets, knit of very firm though slender threads.

Notwithstanding their very friendly disposition, these people have very formidable weapons; some of their spears have many barbs, and must be very dangerous weapons when they take effect. A large flat shell or breastplate was purchased, made of a roundish bone, white and polished like ivory, about 18 inches in diameter, which appeared to have belonged to an animal of the whale tribe.

AMYGDALUS. At the end of the article, for n° 99. read *The Catalogue of Simples*.

AMYLACEOUS, from *amylum*, "starch;" a term applied to the fine flour of farinaceous seeds, in which consists their nutritive part. See **BREAD**, (*Encycl.*)

ANACARDIUM, (*Encycl.*). See also **CASHEW-NUT**, (*Encycl.*)

ANALYSIS, (*Encycl.*) Rhetorical analysis, is that which examines the connections, tropes, figures, and the like, inquiring into the proposition, division, passions, arguments, and other apparatus of rhetoric.

Several authors, as Freigius and others, have given analyses of Cicero's Orations, wherein they reduce them to their grammatical and logical principles; strip them of all the ornaments and additions of rhetoric which

Analysis
||
Antimony.

which otherwise disguise their true form, and conceal the connection between one part and another. The design of these authors is to have those admired harangues just such as the judgment disposed them, without the help of imagination; so that here we may coolly view the force of each proof, and admire the use Cicero made of rhetorical figures to conceal the weak part of a cause.

A collection has been made of the analyses formed by the most celebrated authors of the 16th century, in 3 vols folio.

ANALYSIS is also used, in chemistry, for the decomposing of a mixed body, or the separation of the principles and constituent parts of a compounded substance.

To analyze bodies, or resolve them into their component parts, is indeed the chief object of the art of chemistry. Chemistry furnishes several means for the decomposition of bodies, which are all founded on the differences of the properties belonging to the different principles of which the body to be analyzed is composed. If, for example, a body be composed of several principles, some of which have a great, and others a moderate degree of volatility, and, lastly, others are fixed, its most volatile parts may be first separated by a gradual heat in distilling vessels; and then the parts which are next in volatility will pass over in distillation; and lastly, those parts which are fixed, and capable of resisting the action of fire, will remain at the bottom of the vessel.

ANALYSIS is also used for a kind of syllabus, or table of the principal heads or articles of a continued discourse, disposed in their natural order and dependency. Analyses are more scientific than alphabetical indexes; but they are less used, as being more intricate.

ANALYSIS is likewise used for a brief, but methodical, illustration of the principles of a science; in which sense it is nearly synonymous with what we otherwise call a *synopsis*.

ANASARCA, (*Encycl.*) *See* the references.—In this distemper the water is contained in the cellular membrane between the skin and flesh. Its cure is the same with that of the ascites. *See* MEDICINE, n° 441—444. and p. 4870. col. 2. (*Encycl.*)

ANEMONE, (*Encycl.*) Horned cattle, when removed from the higher grounds into woods and woody pastures, frequently eat the wood-anemone; and, according to Linnæus and Gunner, many observations have proved that it causes the bloody flux among them.

ANTIQUITIES. Marginal note: For VII. read *Antiquities* III.

Apple.

ANVIL, (*Encycl.*) a smith's utensil, serving to place their work on to be hammered or forged. The face or uppermost surface of the anvil must be very flat and smooth, without flaws; and so hard that a file will not touch it.—At one end is sometimes a pike, bickern or beak-iron, for the rounding of hollow work. The whole is usually mounted on a firm wooden block.

APHIS*, (*Encycl.*) These insects are found in great numbers on the stems, leaves, and even roots of many trees and plants. Those trees that are most loaded with the insects, suffer greatly from them. The plant-lice thrust their sharp-pointed rostrum into the substance of the leaf to draw out their sustenance, which warps the stems and leaves, and occasions in the latter cavities underneath, and swellings above; nay, even in some, a kind of hollow gall filled with insects, as is often seen on elm-leaves.

It appears astonishing, that the slight puncture of so small an animal should so greatly disfigure a plant: but it must be remembered, that plant-lice always live in numerous associations, which increase visibly by the prodigious fruitfulness of those insects; so that altho' each puncture be slight, yet the number of them is so great, so reiterated, that it is no longer a wonder the leaves should be disfigured. And indeed lovers of gardening and plants seek to free and cleanse their trees from this vermin; but their care often proves unavailing, the insect is so fruitful that it soon produces a fresh colony. The best and surest method of extirpating it, is to put on the trees infested with them some larvæ of the plant-louse-lion, or aphidivorous flies †; for those voracious larvæ destroy every day a great number of the insects, and that with so much the more facility, as the latter remain quiet and motionless in the neighbourhood of these dangerous enemies, who range over heaps of plant-lice, which they gradually waste and diminish.

APIS, (*Encycl.*) *See* also BEE.—P. 515. col. 1. par. 2. for n° 2. read n° 21. And p. 554. col. 1. line 31. for fig. 12. read fig. 17.

APPLE, (*Encycl.*) For *Malus* read *Pyrus*.

The best method of preserving apples for winter use, is to let them hang upon the trees until there is danger of frost, to gather them in dry weather, and then to lay them in large heaps to sweat for a month or six weeks. They ought then to be carefully looked over, all which have the least appearance of decay taken out, the sound fruit wiped dry, and packed up in large oil jars, which have been thoroughly calded and dry, and then stopped close to exclude the air. If this plan is duly observed, the fruit will keep a long time sound, and their flesh remain plump; whereas, when exposed to the air, their skins will shrivel, and their pulp soften.

Among the various kinds of apples, some are used for the dessert, some for the kitchen, and some for cyder-making. Those used for the dessert are the following, placed as they successively ripen after one another: The white juncating, the margaret apple, the summer pearmain, the summer queening, the embroidered apple, the golden rennet, the summer white calville, the summer red calville, the silver pippen, the aromatic

* See Plate CCCXIII.

† See *Coccinella*, *Ichneumon*, *Hemerobius*, &c. (Appendix.)

Apple
||
rchbishop

aromatic pippin, *la reinette* apple, *la haute bonte*, the royal ruffletting. Wheeler's rufflet, Sharp's rufflet, the spine apple, the golden pippin, the nonpareil, *l'api* or *pomme d'api*.

Those for the kitchen use, in the order of their ripening are these: The codling, the summer margold, the summer red pearmain, the Holland pippin, the Kentish pippin, the courpendu, Loan's pearmain, the French rennet, the French pippin, the royal rufflet, the monstrous rennet, the winter pearmain, the *pomme violette*, Spencer's pippin, the stone pippin, and the oaken pippin.

Those most esteemed for cyder are, the Devonshire royal wilding, the redstreak apple, the whitfleur, the Herefordshire under-leaf, and the John apple, or *deux ames*, everlasting hanger, and genet moyle.

The apple is composed of four distinct parts, viz. the pill, the parenchyma, the branchery, and the core. The pill or skin is only a dilatation of the outermost skin or rind of the bark of the branch on which it grew. The parenchyma or pulp, as tender and delicious as it is found, is only a dilatation, or, as Dr Grew calls it, a *swellth* or superbiency of the inner part of the bark of the branch. This appears not only from the visible continuation of the bark from the one through the pedicle or stalk to the other, but also from the structure common to both. The branchery or vessels, are only ramifications of the woody part of the branch, sent throughout all the parts of the parenchyma, the greater branches being made to communicate with each other by insinuations of the less.

The apple core is originally from the pith of the branch; the sap of which finding room enough in the parenchyma through which to diffuse itself, quits the pith, which by this means hardens into core.

The juice of apples is a menstruum for iron. A solution of iron in the juice of the apples called *golden rennets*, evaporated to a thick consistence, proves an elegant chalybeate, which keeps well.

ARCHBISHOP, (*Encycl.*) Archbishops were not known in the east till about the year 320; and though there were some soon after this who had the title, yet that was only a personal honour, by which the bishops of considerable cities were distinguished. It was not till of late that archbishops became metropolitans, and had suffragans under them. Athanasius appears to be the first who used the title *archbishop*, which he gave occasionally to his predecessor; Gregory Nazianzen, in like manner, gave it to Athanasius; not that either of them were intitled to any jurisdiction, or even any precedence, in virtue of it. Among the Latins, Isidore Hispalensis is the first that speaks of archbishops. He distinguishes four orders or degrees in the ecclesiastical hierarchy, viz. patriarchs, archbishops, metropolitans, and bishops.

The archbishop, beside the inspection of the bishops and inferior clergy in the province over which he presides, exercises episcopal jurisdiction in his own diocese. He is guardian of the spiritualities of any vacant see in his province, as the king is of the tempo-

ralities; and exercises ecclesiastical jurisdiction in it, Archbishops He is intitled to present by lapse to all the ecclesiastical livings in the disposal of his diocesan bishop, if not filled within six months. He has likewise a customary prerogative, upon consecrating a bishop, to name a clerk or chaplain to be provided for by such bishop; in lieu of which it is now usual to accept an option. He is said to be enthroned when vested in the archbishopric; whereas bishops are said to be installed.

The archbishop of Canterbury had anciently, viz. till the year 1152, jurisdiction over Ireland as well as England, and was stiled a *patriarch*, and sometimes *alterius orbis papa*, and *orbis Britannici pontifex*. Matters were done and recorded in his name thus, *Ann pontificatus nostri primo*, &c. The first archbishop of Canterbury was Austin, appointed by king Ethelbert, on his conversion to Christianity, about the year 598. He was also *legatus natus*. He even enjoyed some special marks of royalty; as, to be patron of a bishoprick, which he was of Rochester; and to make knights, coin moneys, &c. He is still the first peer of England, and the next to the royal family; having precedence of all dukes and all great officers of the crown. It is his privilege, by custom, to crown the kings and queens of this kingdom. He may retain and qualify eight chaplains; whereas a duke is by statute allowed only six. He has, by common law, the power of probate of wills and testaments, and granting letters of administration. He has also a power to grant licences and dispensations in all cases formerly sued for in the court of Rome, and not repugnant to the law of God. He accordingly issues special licences to marry, to hold two livings, &c. and he exercises the right of conferring degrees. He also holds several courts of judicature; as, court of arches, court of audience, prerogative court, and court of peculiars.

The archbishop of York has the like rights in his province as the archbishop of Canterbury. He has precedence of all dukes not of the royal blood; and of all officers of state, except the lord high chancellor. He has also the rights of a count palatine over Hexamshire. The first archbishop of York was Paulinus, appointed by Pope Gregory about the year 622. He had formerly jurisdiction over all the bishops of Scotland; but in the year 1470, pope Sixtus IV. created the bishop of St Andrew's archbishop and metropolitan of all Scotland.

ARGONAUTIC EXPEDITION. See THESSALY; (*Encycl.*) This celebrated voyage, which is the first epoch in the Grecian history upon which any stress can be laid, was undertaken, according to Archibishop Usher and the authors of the Universal History, 1280 B. C. Dr Blair places it 1263; and Sir Isaac Newton and Dr Priestley 936 years before the same period; but all chronologers agree in fixing this enterprise near a century before the Trojan war.

Dr Bryant rejects the history of the Argonautic expedition as a Grecian fable, founded indeed on a tradition.

Archbishop
||
Argonautic

Arillus, dition derived from Egypt, and ultimately referring to Armstrong.
 Noah's preservation, &c. in the ark.

ARILLUS, an improper term invented by Linnaeus, and defined to be the proper exterior coat or covering of the seed, which falls off spontaneously.

All seeds are not furnished with an arillus; in many, a dry covering, or scarf-skin, supplies its place. In Jessamy; hound's tongue, *cynoglossum*; cucumber; fraxinella, *dictamnus*; staff-tree, *calafirus*; spindle-tree, *eunymus*; African spiræa, *diosua*; and the coffee-tree, *coffea*; it is very conspicuous.

In the genus hound's tongue, four of these arilli, or proper coats, each inclosing a single seed, are affixed to the style or pointal; and in this circumstance, says Linnaeus, does the essence of the genus consist. In fraxinella, the arillus is common to two seeds. The staff-tree has its seeds only half involved with this cover.

The arillus is either

Baccatus, succulent, and of the nature of a berry; as in the spindle tree, *eunymus*.

Cartilagineus, cartilaginous, or gristly; as in the African spiræa, *diosua*.

Coloratus, coloured; as in the staff-tree.

Elasticus, endued with elasticity, for dispersing the seeds; as is remarkable in the African spiræa, *diosua*, and fraxinella.

Scaber, rough and knotty; as in hound's-tongue.

Although covered with an arillus, or other dry coat, seeds are said to be naked (*semina nuda*), when they are not inclosed in any species of pericarpium or fruit-vessel; as in the grasses, and the *labiati* or lipped flowers of Tournefort, which correspond to the *Didynamia Gynouspermia* of Linnaeus.

Seeds are said to be covered (*semina testæ*) when they are contained in a fruit-vessel, whether capsule, pod, or pulpy pericarpium, of the apple, berry, or cherry kind. See SEMEN, (*Encycl.*)

This exterior coat of the seed is, by some former writers, styled *Calyptra*. See CALYPTRA, (*Encycl.*)

The different skins or coverings of the seed, are adapted, say naturalists, for receiving the nutritive juices, and transmitting them within.

ARMSTRONG, (Dr John), an eminent physician, poet, and miscellaneous writer, was born in Castleton parish, Roxburghshire, where his father and brother were ministers; completed his education in the university of Edinburgh, where he took his degree in physic, Feb. 4. 1732, with much reputation; and published his thesis, as the forms of that university require; the subject was *De tabe purulenta*. In 1735 he published a little humorous fugitive pamphlet in 8vo, entitled, *An Essay for abridging the Study of Physic; to which is added a Dialogue betwixt Hygeia, Mercury, and Pluto, relating to the Practice of Physic, as it is managed by a certain illustrious Society. As also an Epistle from Usbek the Persian to Joshua Ward, Esq.* This piece contains much fun and drollery; in the dialogue, he has caught the very spirit of Lucian. In 1737 he published *A Synopsis of the History and Cure of the Venereal Diseases*, 8vo. This was soon followed by the *Oeconomy of Love*: a poem which has much merit; but, it must be confessed, is too strongly tinged with the licentiousness of Ovid. It is said, however, that his maturer judgment expunged many of the luxuriances of youthful fancy, in an edition "re-

vised and corrected by the author" in 1768. It appears by one of the cases on literary property, that Mr Millar paid 50 guinea for the copy-right of this poem, which was intended as a burlesque on some didactic writers. It has been observed of Dr Armstrong, that his works have great inequalities, some of them being possessed of every requisite to be sought after in the most perfect composition, while others can hardly be considered as superior to the productions of mediocrity. The *Art of preserving Health*, his best performance, which was published in 1744, will transmit his name to posterity as one of the first English writers, has been honoured with the following testimony of a respectable critic. On this work we shall also transcribe a beautiful eulogium from an eminent physician*: "Of all the poetical performances on this subject that have come to my hands, Dr Armstrong's *Art of preserving Health* is by far the best. To quote every charming description and beautiful passage of this poem, one must transcribe the whole. We cannot, however, expect new rules, where the principal design was to raise and warm the heart into a compliance with the solid precepts of the ancients, which he has enforced with great strength and elegance. And, upon the whole, he has convinced us, by his own example, that we ought not to blame antiquity for acknowledging

One power of physic, melody, and song."

In 1746 Dr Armstrong was appointed one of the physicians to the hospital for lame and sick soldiers behind Buckingham house. In 1751 he published his poem on Benevolence, in folio; and in 1753, "Taste, an epistle to a young Critic." In 1758 appeared, "Sketches, or Essays on various subjects, by Launcelot Temple, Esq; in two parts." In this production which possesses much humour and knowledge of the world, and which had a remarkably rapid sale, he is supposed to have been assisted by Mr Wilkes. In 1760 he had the honour of being appointed physician to the army in Germany; where in 1761 he wrote a poem called "Day, an Epistle to John Wilkes of Aylesbury, Esq;" In this poem, which is not collected in his works, he wantonly hazarded a reflection on Churchill, which drew on him the serpent-toothed vengeance of that ferocious satirist, whose embalming or corrosive pen could deify or lampoon any man, according as he acquiesced with, or dissented from, his political principles. In 1770 Dr Armstrong published a collection of "Miscellanies in 2 vols; containing, 1. The Art of preserving Health. 2. Of Benevolence, an Epistle to Eumenes. 3. Taste, an Epistle to a young Critic, 1753. 4. Imitations of Shakspear and Spenser. 5. The Universal Almanac, by Nouredin Ali. 6. The Forced Marriage, a tragedy. 7. Sketches." In 1771 he published "A short Ramble through some Parts of France and Italy, by Launcelot Temple;" and in 1773, in his own name, a quarto pamphlet, under the title of *Medical Essays*; towards the conclusion of which, he accounts for his not having such extensive practice as some of his brethren, from his not being qualified to employ the usual means, from a ticklish state of spirits, and a disordered excess of sensibility. He complains much of the behaviour of some of his brethren, of the herd of critics, and particularly of the reviewers. He died in September 1779; and, to the

ASPERIFOLIE PLANTÆ, rough leaved plants. The name of a class in Hermannus, Boerhaave, and Ray's Methods, consisting of plants which have four naked seeds, and whose leaves are rough to the touch.

In Tournefort's System, these plants constitute the third section or order of the second class; and in Linnaeus's Sexual Method, they make a part of the pentandria monogynia.

ASPHODELUS, (Encycl.) The Lancashire asphodel is thought to be very noxious to sheep, whenever, through poverty of pasture, they are necessitated to eat it; although they are said to improve much in their flesh at first, they afterwards die with symptoms of a diseased liver. This is the plant of which such wonderful tales have been told by Pauli, Bartholine, and others, of its softening the bones of such animals as swallow it; and which they thence called *gramen ossifragum*. Horned cattle eat it without any ill effect.

ASSETS, in law, signifies goods enough to discharge that burthen which is cast upon the executor or heir, in satisfying the debts and legacies of the testator or ancestor. Assets are real or personal; where a man hath lands in fee simple, and dies seised thereof, the lands which come to his heir are assets real: and where he dies possessed of any personal estate, the goods which come to the executors are assets personal. Assets are also divided into *assets per descent*, and *assets inter maines*. Assets by descent is where a person is bound in an obligation, and dies seised of lands which descend to the heir, the land shall be assets, and the heir shall be charged as far as the land to him descended will extend. *Assets inter maines* is when a man indebted makes executors, and leaves them sufficient to pay his debts and legacies; or where some commodity or profit ariseth to them in right of the testator, which are called *assets in their hands*.

ASTERN, a sea-phrase, used to signify any thing at some distance behind the ship; being the opposite of AHEAD, which signifies the space before her. See AHEAD, (Encycl.)

ATMOSPHERE, (Encycl.) See also AIR in this APPENDIX.—The lately discovered art of navigating the atmosphere, has ascertained a fact formerly unknown, viz. that in the middle regions of the air, the wind most frequently blows in a direction contrary to that below; that there are there also a kind of eddies or currents which move in a circular direction. When M. Charles ascended by himself, as mentioned under the article AIR-Balloon, p. 9019. he was sensible of these currents; and the opposite direction taken by

the small globe sent off before their first journey ascertains the latter. In this journey also the electricity of the upper parts of the atmosphere was the cause of a curious phenomenon, viz. that the flags he carried with him as signals, instead of hanging down towards the earth, erected themselves in the air.

The Salubrity of the ATMOSPHERE at different heights and in different places has much engaged the attention of philosophers. The air on the tops of mountains is generally more salubrious than that in pits. Dense air indeed is always more proper for respiration than such as is more rare; yet the air on mountains, though much more rare, is more free from phlogistic vapours than that of pits. Hence it has been found, that people can live very well on the tops of mountains, where the barometer sinks to 15 or 16 inches. M. de Saussure, in his journey upon the Alps, having observed the air at the foot, on the middle, and on the summits of various mountains, observes, that the air of the very low plains seems to be the less salubrious; that the air of very high mountains is neither very pure, nor, upon the whole, seems so fit for the lives of men, as that of a certain height above the level of the sea, which he estimates to be about 200 or 300 toises, that is, about 430 or 650 yards.

Dr White, in the lxxviiith vol. of the Phil. Trans. giving an account of his experiments on air made at York, says, that the atmospheric air was in a very bad state, and indeed in the worst he had ever observed it, the 13th of September 1777; when the barometer stood at 30.30; the thermometer stood at 69°; the weather being calm, clear, and the air dry and sultry, no rain having fallen for above a fortnight. A slight shock of an earthquake was perceived that day.

The air of a bed-room at various times, viz. at night, and in the morning after sleeping in it, has been examined by various persons; and it has been generally found, that after sleeping in it, the air is less pure than at any other time. The air of privies, even in calm weather, has not been found to be so much phlogisticated as might have been expected, notwithstanding its disagreeable smell.

From this and other observations, it is thought that the exhalations of human excrements are very little if at all injurious, except when they become putrid, or proceed from a diseased body; in which case they infect the air very quickly.

Dr Ingenhoulz, soon after he left London, sent an account of his experiments made in the year 1779 upon the purity of the air at sea and other parts; which account was read at the Royal Society the 24th of April 1780, and is inserted in the lxxth vol. of the Phil. Trans. His first observations were made on board a vessel in the mouth of the Thames, between Sheerness and Margate, where he found that the air was purer than any other sort of common air he had met with before. He found that the sea air taken farther from the land, viz. between the English coast and Ostend, was not so pure as that tried before; yet this inferior purity seems not to take place always. The Doctor's general observations, deduced from his numerous experiments, are, "That the air at sea, and close to it, is in general purer, and fitter for animal life, than the air on the land, though it seems to be subject to some inconsistency in its degree of purity with that

of the land. "That probably the air will be found in general much purer far from the land than near the shore, the former being never subject to be mixed with land air."

The Doctor in the same paper transcribes a journal of experiments, showing the degree of purity of the atmosphere in various places, and under different circumstances; which we shall insert here in an abridged manner, thinking it of great use to other experimentators.

The method used in those experiments, was to introduce one measure of common air into the eudiometer-tube, and then one measure of nitrous air. The moment that these two sorts of elastic fluids came into contact, he agitated the tube in the water-trough, and then measured the diminution, expressing it by hundredths parts of a measure; thus, when he says that such air was found to be 130, it signifies, that after mixing one measure of it with one of nitrous air, the whole mixed and diminished quantity was 130 hundredths of a measure, viz. one measure and 30 hundredths of a measure more.

"The different degrees of salubrity of the atmosphere, as I found it in general in my country-house at Southall Green, ten miles from London, from June to September, lay between 103 and 109.

"I was surprised, when upon my return to town to my former lodgings in Pall-Mall Court, I found the common air purer in general in October, than I used to find it in the middle of summer in the country; for on the 22d of October, at nine o'clock in the morning, the weather being fair and frosty, I found that one measure of common air, and one of nitrous air, occupied 100 subdivisions in the glass tube, or exactly one measure. That very day, at two o'clock in the afternoon (it being then rainy weather), the air was somewhat altered for the worse. It gave 102.

"October the 23d, it being rainy weather, the air gave 102.

"October the 24th, the weather being serene, the air at nine o'clock in the morning gave 100.

"October the 25th, the sky being cloudy at 11 o'clock in the morning, the air gave 102. At 11 o'clock at night, from five different trials, it gave 105.

"October the 26th, the weather being very dark and rainy, the air gave 105, as before."

The air at Ostend was found by the Doctor to be generally very good, giving between 94 and 98.

At Bruges, the air taken at seven o'clock at night gave 103.

November the 8th, the air at Ghent at three in the afternoon gave 103.

November the 12th, the air of Brussels at seven o'clock P. M. gave 105½.

The next day the air of the lower part of the same city gave 106; that of the highest appeared to be purer, as it gave 104; which agrees with the common popular observation. November the 14th, both the air of the highest and that of the lowest part of the city appeared to be of the same goodness, giving 103. The weather was frosty.

November the 22d, the air of Antwerp in the evening gave 109½; the weather being rainy, damp, and cold.

November the 23d, the air of Breda gave 106. The next day about 11 o'clock the air gave 102; the weather being fair, cold, and inclining to frost. At seven

o'clock it gave 103. Next day, being the 25th, the air gave 104; the weather being cold and rainy. The 26th it gave 103; the weather being very rainy, cold, and stormy.

November the 27th, the air at the Moordyke close to the water gave 101½, the weather being fair and cold, but not frosty. This spot is reckoned very healthy.

November the 28th, the air of Rotterdam gave 103; the weather being rainy and cold.

November the 29th, the air of Delphit gave 103; the weather being stormy and rainy.

November the 30th, the air of the Hague gave 104; the weather being cold, and the wind northerly. The first of December the weather underwent a sudden change; the wind becoming southerly and stormy, and the atmosphere becoming very hot. The day after, Fahrenheit's thermometer stood at 54°; and the common air being repeatedly and accurately tried gave 116; and that preserved in a glass phial from the preceding day gave 117; and that gathered close to the sea gave 115.

December the 4th, the air of Amsterdam gave 103; the weather being rainy, windy, and cold. The day after, the weather continuing nearly the same, the air gave 102.

December the 10th, the air of Rotterdam gave 101; the weather being rainy.

December the 12th, being in the middle of the water between Dort and the Moordyke, the air gave 109; the weather being remarkably dark, rainy, and windy.

December the 13th, the air of Breda in the morning gave 109; the weather continuing as the day before. And in the afternoon, the air gave 106½; the weather having cleared up.

December the 16th, the air of the lower part of the city of Antwerp gave 105; that of the higher part, 104; the weather being rainy and temperate.

December the 17th, the air of Antwerp gave 107; the weather continuing nearly as in the preceding day.

December the 19th, the air of Brussels gave 109; the weather being rainy, windy, and rather warm.

December the 21st, the air of Brussels gave 106; the weather being dry and cold. The next day the air and weather continued the same.

December the 23d, the air of Mons gave 104; the weather being rainy and cold.

December the 24th, the air near Bouchain gave 104½; the weather being cloudy and cold.

December the 25th, the air of Peronne gave 102½; the weather being frosty.

December the 26th, the air of Cu villi gave 103; the weather frosty.

December the 27th, the air of Senlis gave 101½; the weather frosty.

December the 29th, the air of Paris gave 103; the weather frosty.

1780. January the 8th, the air of Paris gave 100; the weather frosty.

January the 13th, the air of Paris gave 98; hard frost.

Thus far with Dr Ingenhoufz's observations. His apparatus was a very portable one, made by Mr Martin, which in reality is the eudiometer-tube and measure as used by Mr Fontana, before he made his last improvement. "The whole of this apparatus

ratus (says Dr Ingenhoufz) was packed up in a box about ten inches long, five broad, and three and a half high. The glass tube or great measure, which was 16 inches long, and divided in two separate pieces, lay in a small compass, and could be put together by brass screws, adapted to the divided extremities. Instead of a water-trough, such as is used commonly, I made use of a small round wooden tub, &c."

The abbe Fontana, who has made a great number of very accurate experiments upon this subject, gives his opinion in the following words. "I have not the least hesitation in asserting, that the experiments made to ascertain the salubrity of the atmospherical air in various places in different countries and situations, mentioned by several authors, are not to be depended upon; because the method they used was far from being exact (A), the elements or ingredients for the experiment were unknown and uncertain, and the results very different from one another.

"When all the errors are corrected, it will be found that the difference between the air of one country and that of another, at different times, is much less than what is commonly believed; and that the great differences found by various observers are owing to the fallacious effects of uncertain methods. This I advance from experience; for I was in the same error. I found very great differences between the results of the experiments of this nature which ought to have been similar; which diversities I attributed to myself, rather than to the method I then used. At Paris I examined the air of different places at the same time, and especially of those situations where it was most probable to meet with infected air, because those places abounded with putrid substances and impure exhalations; but the differences I observed were very small, and much less than what could have been suspected, for they hardly arrived to one fiftieth of the air in the tube. Having taken the air of the hill called *Mount Valerian*, at the height of about 500 feet above the level of Paris, and compared it with the air of Paris taken at the same time, and treated alike, I found the former to be hardly one thirtieth better than the latter.

"In London I have observed almost the same. The air of Ilstington and that of London suffered an equal diminution by the mixture of nitrous air; yet the air of Ilstington is esteemed to be much better. I have examined the air of London taken at different heights, (for instance, in the street, at the second floor, and at the top of the adjoining houses), and have found it to be of the same quality. Having taken the air at the iron gallery of St Paul's cupola, at the height of 313 feet above the ground, and likewise the air of the stone gallery, which is 202 feet below the other; and having compared these two quantities of air with that of the street adjoining, I found that there was scarce any sensible difference between them, although taken at such different heights.

"In this experiment a circumstance is to be considered, which must have contributed to render the above-mentioned differences more sensible: this is, the agitation of the air of the cupola; for there was felt a pretty brisk wind upon it, which I observed to be stronger and stronger the higher I ascended; whereas in the

street, and indeed in all the streets I passed through, there was no sensible wind to be felt. This experiment was made at four in the afternoon, the weather being clear. The quicksilver in the barometer at that time was 28.6 inches high, and Fahrenheit's thermometer stood at 54°."

A few lines after, Mr Fontana proceeds thus:—"From this we clearly see, how little the experiments hitherto published about the differences of common air are to be depended upon. In general, I find that the air changes from one time to another; so that the differences between them are far greater than those of the air of different countries, or different heights; for instance, I have found that the air of London in the months of September, October, and November, 1778, when treated with the nitrous air, gave 11,1, 1,90, and 11,11, 2,25, which is a mean result of many experiments, which differed very little from each other. The 26th day of November last, I found the air for the first time much better, for it gave 11,1, 1,80, and 11,11, 2,20; but the 14th of February, 1779, the air gave 11,1, 1,69, and 11,11, 2,21; from whence it appears, that the air of this 14th of February was better than it had been for six months before.

"There can be no doubt of the accuracy of the experiments, because I compared the air taken at different times with that which I had first used in the month of September, and which I had preserved in dry glass-bottles accurately stoppered."

This difference in the purity of the air at different times, Mr Fontana farther remarks, is much greater than the difference between the air of the different places observed by him; notwithstanding this great change, as he observed, and as he was informed by various persons, no particular change of health in the generality of people, or facility of breathing, was perceived.

Mr Fontana lastly concludes with observing, that "Nature is not so partial as we commonly believe. She has not only given us an air almost equally good every where, at every time, but has allowed us a certain latitude, or a power of living and being in health in qualities of air which differ to a certain degree. By this I do not mean to deny the existence of certain kinds of noxious air in some particular places; but only say, that, in general, the air is good every where, and that the small differences are not to be feared so much as some people would make us believe. Nor do I mean to speak here of those vapours and other bodies which are accidentally joined to the common air in particular places, but do not change its nature and intrinsic property. This state of the air cannot be known by the test of nitrous air; and those vapours are to be considered in the same manner as we should consider so many particles of arsenic swimming in the atmosphere. In this case it is the arsenic, and not the degenerated air, that would kill the animals who ventured to breathe it."

AVIGATO, or AVOCADO Pear. See the next article.

45 N 2

AVO-

(A) It is plain that Dr Ingenhoufz's method is not implied in this remark; since the Doctor's experiments were made long after, and the method used by him was properly that of Mr Fontana.

AVOCATO-PEAR *Tree*, or *Laurus Persea*; a species omitted to be described under the article *Laurus*. (*Encycl.*)

It is a native of the West Indies. In form and thickness the fruit resembles a pear. The pulpy and fleshy part is of a pale green, with little or no consistence when ripe, and melts in the mouth like marrow, which it greatly resembles in taste. The skin is smooth and thin, but of a strong tough substance, and of a beautiful green colour, which does not become yellow till the fruit is perfectly ripe. The fruit, by reason of its softness, may be eaten out of the surrounding skin with a tea-spoon, like jelly and marmalade. It is frequently served up in the West Indies on a plate, with sugar, rose-water, and orange-flowers; most commonly, however, it is mixed with sugar and the juice of limes, which render it extremely palatable.

The unripe fruit too is frequently plucked and eaten in thin slices, with pepper and salt. In this stage, the taste of the avocado greatly resembles that of artichokes. Every preparation of this fruit is esteemed highly nourishing; as it warms, exhilarates, and fortifies the stomach.—It is particularly recommended in dysenteries.

In the middle of the pulpy part of the fruit lies the nut or seed, which is very large, almost round, of a pale russet colour, a little wrinkled, contains no kernel within it, and whose degree of hardness does not exceed that of a chestnut divested of its skin. This nut, about an hour after it is separated from the fruit, splits of itself into two or three pieces. If committed to the ground in this state, no vegetation ensues, because the embryo of the seed is broken; so that such as would propagate these plants from seed must sow the nuts the moment they are taken out of the pulp, in which case they will begin to germinate in eight or ten days after.

The bark and wood of this tree, which rises to a considerable height, are of a greyish colour. The leaves are long, pointed, of a substance like leather, and of a beautiful green colour. The flowers are produced in large knots or clusters at the extremities of the branches, and consist each of six petals disposed in the form of a star, and of a dirty white or yellow colour, with an agreeable odour, which diffuses itself to a considerable distance. The tree begins to bear fruit

two years and a half, or at most three years after being planted; and like most of the trees in warm climates, bears twice a year.

The buds of the avocado tree are said to be used with success in pitans against the venereal disease. An infusion of them in water, drank in the morning fasting, is strongly recommended for dissolving coagulated blood in the stomach produced by a fall or a severe stroke on that important entrail. “The wild boars in the East Indies (says Labat) eat greedily of the mammees and avigato pears, which give their flesh a luscious and most agreeable flavour.”

AURORA, one of the New Hebrides islands in the South Sea, in which Mr Foster supposes the *Peak d’Etoile* mentioned by Mr Bougainville to be situated. The island is inhabited; but none of its inhabitants came off to visit captain Cook. The country is woody, and the vegetation seemed to be excessively luxuriant. It is about 12 leagues long, but not above five miles broad in any part; lying nearly north and south. The middle lies in S. Lat. 15. 6. E. Long. 168. 24.

AURUM FULMINANS, (*Encycl.*) See *Fulminating GOLD*.—It has been thought that this substance, which explodes with an astonishing violence, and makes a very sharp report, would produce a far greater effect than gun-powder, if it were cheap enough to be used as a substitute for fire-arms. But repeated experiments have shown, that when fulminating gold is confined in the barrel of a pistol, in a hollow iron ball, or the like, its effects are much inferior to those of gun-powder; and the reason is, because fulminating gold produces an incomparably less quantity of elastic fluid than gun-powder does. The surprising effects produced by it when fulminating in the open air, according to Mr Cavallo, must be owing to the sudden generation of the elastic fluid, and not to the quantity of it produced. Bergman says, that the elastic fluid generated by fulminating gold is scarcely equal to four times the bulk of the fulminating gold. He also says, that half a drachm of fulminating gold, fired in a close vessel, makes a report hardly audible; and that the elastic fluid it generates, extinguishes flame, is noxious to animals, is not absorbed by water, nor renders lime-water turbid.—These are the characteristic properties of phlogisticated air.

BAMBOO. See *ARUNDO* and *BAMBOO*, (*Encycl.*) This tree, the *ily* or *illi* of the *Hortus Malabaricus*, grows naturally in sandy places, and on the banks of rivers in both Indies; where it frequently attains a height exceeding even that of the cocoa-tree. The root is not very different from the stem, unless that it is of a whitish colour, and consists of several ra-

dicles or fibres. From the joints of the main root are emitted small jointed stalks, which again emit others from their joints; and from these, as from so many new roots, arise several stalks joined together; which being planted with their radicles or string-roots, serve to perpetuate the species. These stalks are round, have a green bark; are hard, emit from the joints new branches and twigs, and are armed in the joints themselves with one, two, or more, rigid and acute thorns of an oblong figure. It is to be observed, however, that the stalks in question, arising, as we have said, immediately from the root, have attained in their native soil the height of two or three men, and the thickness of almost a span, before they send forth any lateral branches. These, when young and tender, are nearly solid, pervious only in the middle by a small tube

bamboo.

tube. The older stalks and branches are hollow within, being shut, however, at the joints with a woody partition, and covered internally with a slender whitish membrane that is composed of hard white woody filaments. The colour of the stalks, when young, is a brownish green; when older, a shining yellow, with a shade of white. The leaves are long, narrow, seated on short foot-stalks, streaked with longitudinal veins, and rough on the edges if rubbed downwards. The flowers grow in long scaly spikes, which proceed in great numbers from the joints of the stalks. Rheede mentions a tradition prevailing on the coast of Malabar, that the bamboo vegetates till its 60th year; at which period of its growth, and nearly a month before the flowers emerge from their scaly covers, the tree is divested of all its leaves; and after it has ceased to flower, immediately dies. This tree or reed is termed by the inhabitants of Ceylon, *unaghar*, that is, "fever-tree," from an opinion generally entertained in that island, that a fever is the certain consequence of bathing in any river into which the flowers or leaves of the bamboo have fallen. By the Arabians it is named *tabaxir*; as is likewise a milky humour or sugar produced in it. The Indians call it *mambu*; whence vulgarly, and by corruption, its European name of *bamboo* or *bambou*. In the island of Madagascar, and particularly in the province of Galemoulou, by the testimony of Flacourt, it is produced in such abundance as to give name to the province, for in those parts it is termed *voulu*. The size of this tree in India is generally so great, that houses are built of it. In the porch of the acedemical garden at Leyden are suspended some fragments, a present of the celebrated Piso, the largest of which exceeds 28, the least 26, feet in length. That they must, however, have been double that size before they were broken off, appears probable from this circumstance, that the thickness of one extremity scarce differs from that of the other. It is likewise wonderful that so immense a reed should be clothed with so very small leaves; the largest of the dried ones in the collection of Professor Syens at Leyden, mentioned by Rheede in his *Hortus Malabaricus*, scarcely exceeding a span in length, or the breadth of a finger in width. The stalks, when old, are entirely covered in the cavity with a sort of calx, which is esteemed useful in the stranguary, and to such as are troubled with purulent urine. Bamboo being burnt, affords very fertile ashes, in which plants of all kinds thrive remarkably. Whilst burning, the stalks emit a very loud explosion; the air contained in their cavity being rarefied by the heat, and desiring a larger space, breaks thro' the partitions at the joints, and violently seeks a passage whereby to escape. Kempter relates, in the *Amenitates Exoticæ*, that in a province of Japan called *Omi*, which has a slimy bottom, the roots of bamboo luxuriate with such wonderful beauty, that, being dug out of the ground and disentangled from the strings which encompass them, they serve, as the stalks with us, for walking-sticks, commonly called *relang*. From this curious reed several conveniences are obtained besides those which have been mentioned. The reader is referred for a more minute detail, to the *Mantissa Aromatica* of Piso; where, besides a very accurate description of the tabaxir or sugar mentioned above, he will also learn, that the tender branches or twigs,

particularly those near the root, being macerated in salt and vinegar, afford, with the addition of garlic and the pods of capscum, a sort of pickle, which is esteemed excellent, and constitutes not the least valuable part of those famous condita commonly termed *acbar* and *atjaar*, and well known in Europe for exciting the appetite and promoting digestion.

BAMFF, (*Encycl.*) By mistake, this place was said to have no harbour. The following account is given by Mr Pennant: "It is pleasantly situated on the side of a hill; has several streets; and that with the town-house in it, adorned with a new spire, is very handsome. This place was erected into a borough by virtue of a charter from Robert II. dated October 7. 1372, endowing it with the same privileges, and putting it on the same footing with the burgh of Aberdeen; but tradition says it was founded in the reign of Malcolm Canmore. The harbour is very bad, as the entrance at the mouth of the Devon is very uncertain, being often stopped by the shifting of the sands, which are continually changing in great storms; the pier is therefore placed on the outside. Much salmon is exported from hence. About Troophead some kelp is made; and the adventurers pay the lord of the manor 50*l.* per annum for the liberty of collecting the materials."

BANDITTI, (*Encycl.*) from the Italian *bandito*; persons proscribed, or, as we call it, outlawed: sometimes denominated *banitti* or *foris-banitti*. It is also a denomination given to highwaymen or robbers who infest the roads in troops, especially in Italy, France, and Sicily. Mr Brydone, in his Tour through Sicily, informs us, that in the eastern part, called *Val Demoni*, from the devils that are supposed to inhabit Mount *Ætna*, it has ever been found altogether impracticable to extirpate the banditti; there being numberless caverns and subterraneous passages round that mountain, where no troops could possibly pursue them; besides, they are known to be perfectly determined and resolute, never failing to take a dreadful revenge on all who have offended them. Hence the prince of Villa Franca has embraced it, not only as the safest, but likewise as the wisest and most political scheme, to become their declared patron and protector: and such of them as think proper to leave their mountains and forests, though perhaps only for a time, are sure to meet with good encouragement and a certain protection in his service, where they enjoy the most unbounded confidence, which, in no instance, they have ever yet been found to make an improper or a dishonest use of. They are clothed in the prince's livery, yellow and green, with silver lace; and wear likewise a badge of their honourable order, which entitles them to universal fear and respect from the people.

In some circumstances, these banditti are the most respectable people of the island, and have by much the highest and most romantic notions of what they call their point of honour. However criminal they may be with regard to society in general; yet, with respect to one another, and to every person to whom they have once professed it, they have ever maintained the most unshaken fidelity. The magistrates have often been obliged to protect them, and pay them in court, as they are known to be perfectly determined and desperate, and so extremely vindictive, that they

will

Bandy,
Barilla.

will certainly put any person to death that has ever given them just cause of provocation. On the other hand, it never was known that any person who had put himself under their protection, and showed that he had confidence in them, had cause to repent of it, or was injured by any of them in the most minute trifle; but, on the contrary, they will protect him from impositions of every kind, and scorn to go halves with the landlord, like most other conductors and travelling servants, and will defend him with their lives if there is occasion. Those of their number who have thus enlisted themselves in the service of society, are known and respected by the other banditti all over the island; and the persons of those they accompany are ever held sacred. For these reasons, most travellers choose to hire a couple of them from town to town; and may thus travel over the whole island in safety.

BANDY-LEGGED. See *VALGUS*, (*Encycl.*)

BARILLA, or **BARILLA**, the name of a plant cultivated in Spain for its ashes, from which the purest kinds of mineral alkali are obtained.

There are four plants, which, in the early part of their growth, bear so strong a resemblance to each other as would deceive any but the farmers and nice observers. These four are, *barilla*, *gazul*, (or, as some call it, *algazul*), *soza*, and *salicornia* or *salicor*. They are all burnt to ashes; but applied to different uses, as being possessed of different qualities. Some of the roguish farmers mix more or less of the three last with the first; and it requires a complete knowledge of the colour, taste, and smell of the ashes to be able to detect their knavery.

Barilla is sown afresh every year. Its greatest height above ground is four inches: each root pushes out a vast number of little stalks, which again are subdivided into smaller sprigs resembling samphire; and all together form a large spreading tufted bush. The colour is bright green; as the plant advances towards maturity, this colour vanishes away till it comes at last to be a dull green tinged with brown.

Gazul bears the greatest affinity to *barilla*, both in quality and appearance: the principal difference consists in its growing on a still drier saltier earth, consequently it is impregnated with a stronger salt. It does not rise above two inches out of the ground, spreading out into little tufts. Its sprigs are much flatter and more pulpy than those of *barilla*, and are still more like samphire. It is sown but once in three, four, or five years, according to the nature of the soil.

Soza, when of the same size, has the same appearance as *gazul*; but in time grows much larger, as its natural soil is a strong salt marsh, where it is to be found in large tufts of sprigs, treble the size of *barilla*, and of a bright green colour, which it retains to the last.

Salicor has a stalk of a deep green colour inclining to red, which last becomes by degrees the colour of the whole plant. From the beginning it grows upright, and much resembles a bush of young rosemary. Its natural soil is on the declivities of hills near the salt marshes, or on the edges of the small drains or channels cut by the husbandmen for the purpose of watering the fields: before it has acquired its full growth, it is very like the *barilla* of those seasons in which the ground has been dunged before sowing. In those years of manuring, *barilla*, contrary to its usual na-

ture, comes up with a tinge of red; and when burnt falls far short of its wonted goodness, being bitter, more impregnated with salts than it should be, and raising a blister if applied for a few minutes to the tongue. *Barilla* contains less salt than the others; when burnt, it runs into a mass resembling a spongy stone, with a faint cast of blue.

Gazul, after burning, comes as near *barilla* in its outward appearance as it does while growing in its vegetable form; but, if broken, the inside is of a deeper and more glossy blue. *Soza* and *salicor* are darker, and almost black within, of a heavier consistence, with very little or no sign of sponginess.

All these ashes contain a strong alkali; but *barilla* the best and purest, though not in the greatest quantity. Upon this principle, it is fittest for making glass and bleaching linen; the others are used in making soap. Each of them would whiten linen; but all, except *barilla*, would burn it. A good crop of *barilla* impoverishes the land to such a degree, that it cannot bear good *barilla* a second time, being quite exhausted. For this reason the richer farmers lay manure upon the ground, and let it lie fallow for a season; at the end of which it is sown afresh without any danger, as the weeds that have sprung up in the year of rest have carried off all the pernicious effects of the dung. A proper succession of crops is thus secured by manuring and fallowing the different parts of the farm, each in their turn. The poorer tribe of cultivators cannot pursue the same method for want of capital; and are therefore under the necessity of sowing their lands immediately after manuring, which yields them a profit just sufficient to afford a present scanty subsistence, though the quality and price of their *barilla* be but trifling.

The method used in making *barilla* is the same as that followed in Britain in burning kelp. The plant as soon as ripe is plucked up and laid in heaps, then set on fire. The salt juices run out below into an hole made in the ground, where they run into a vitrified lump, which is left about a fortnight to cool. An acre may give about a tun.

BAROMETER, (*Encycl.*) A considerable improvement on the wheel-barometer† is that of Mr† See *Barometer*, n° 24. Fitzgerald, F. R. S. It is furnished with two pulleys that move on friction-wheels; each of which turns an index on the centre of a graduated circle. The smaller circle is four inches in diameter, and divided into three equal parts, each of which is again subdivided decimally; and the changes corresponding to the rise or fall of the mercury from 28 to 31 inches, are marked on the margin of it, as they are on the scales of common barometers. The larger circle is divided into 300 equal parts; and being about 30 inches in circumference, the index belonging to it will mark distinctly the 600th part of an inch in the rise or fall of the mercury. On the centre of this circle two registers are fixed, which are placed along the index when the instrument is adjusted; one of them is carried round with the index, and left behind on its return; so that their distance will determine the limits of the variation from one observation to another.

Mr Passlemon, an ingenious artist at Paris, has invented a *marine barometer*, by twisting the middle part of the common one into a spiral consisting of two revolutions.

Barilla,
Barometer.

volutions. Thus the impulses which the mercury receives from the motions of the ship are destroyed, by being transmitted in contrary directions.

Notwithstanding the amazing pains which Mr de Luc has taken to remove every inaccuracy in the barometer, it is not yet entirely free from error; nor do the observations made by different persons altogether correspond. Considerable improvements have been made by Col. Roy and Sir George Shuckburgh, of which an account is given in the 67th and 68th vols of the Philosophical Transactions.

FIRE-BARRELS. See *FIRE-Ship*, note B, (*Encycl.*)

BASKERVILLE (John), an eminent artist, especially in letter-founding and printing, of the present century. He was born in 1706 at Woverley in Worcester-shire, and was heir to an estate of about 60 l. a-year; the whole of which income he allowed to his parents till their deaths. In his early years he conceived a love for fine writing, and cutting in stone; and being brought up to no particular profession, he commenced writing master in Birmingham when about 20 years of age. The improvements in different manufactures there soon drew his attention, and he applied to the Japan business, which he carried on for a long time with distinguished excellence and success. In 1750 he applied himself to letter-founding, the bringing of which to perfection cost him much labour and expence. In a few years he proceeded to printing; and his first work was an edition of Virgil on royal quarto, which now sells for three guineas. In a short time he obtained leave from the university of Cambridge to print a Bible in royal folio, and editions of the Common Prayer in three sizes; for which he paid a large sum to the university. He afterwards printed Horace, Terence, Catullus, Lucretius, Juvenal, Sallust, and Florus, in royal quarto; Virgil in octavo; and several books in duodecimo. He published likewise some of the English classics. The best testimonies of the merit of these performances are themselves; and Mr Baskerville's name is deservedly ranked among those who, in modern times, have brought the art of printing to its greatest perfection. Not meeting, however, with that encouragement from the booksellers which he expected, he set up a letter-foundry for sale a little before his death; which business is now carried on by his widow. He died without issue in July 1775.

BASTARD. (*Encycl.*) This article contains the state of the matter according to the law of England. How it stands in the law of Scotland, see *LAW*, Part III. N° clxxxii. 3. 4. and clxi. 33.

KNIGHTS of the BATH, a military order in England, supposed to have been instituted by Richard II. who limited their number to four; however, his successor Henry IV. increased them to 46. Their motto was *Tres in uno*, signifying the three theological virtues.

This order received its denomination from a custom of bathing before they received the golden spur. It is seldom conferred but at the coronation of kings, or the inauguration of a prince of Wales, or duke of York. They wear a red ribband beltwife.—The order of the Bath, after remaining many years extinct, was revived under George I. by a solemn creation of a great number of knights.

BERWICK. (*Encycl.*) The town of Berwick upon Tweed was originally part of the kingdom of Scotland; and, as such, was for a time reduced by king Edward I. into the possession of the crown of England; and, during such its subjection, it received from that prince a charter, which (after its subsequent cession by Edward Baliol, to be for ever united to the crown and realm of England) was confirmed by king Edward III. with some additions; particularly, that it should be governed by the laws and usages which it enjoyed during the time of king Alexander, that is, before its reduction by Edward I. Its constitution was new-modelled, and put upon an English footing by a charter of king James I. and all its liberties, franchises, and customs, were confirmed in parliament by the statutes 22 Edw. IV. c. 8. and 2 Jac. I. c. 28. Though, therefore, it hath some local peculiarities, derived from the ancient laws of Scotland; yet it is clearly part of the realm of England, being represented by burgesses in the house of commons, and bound by all acts of the British parliament, whether specially named or otherwise. And therefore it was (perhaps superfluously) declared by stat. 20 Geo. II. c. 42. that where England only is mentioned in any act of parliament, the same notwithstanding hath and shall be deemed to comprehend the dominion of Wales and town of Berwick upon Tweed. And though certain of the king's writs or process of the courts of Westminster do not usually run into Berwick, any more than the principality of Wales; yet it hath been solemnly adjudged, that all prerogative writs (as those of *mandamus*, prohibition, *habeas corpus*, *certiorari*, &c.) may issue to Berwick as well as to every other of the dominions of the crown of England, and that indictments and other local matters arising in the town of Berwick may be tried by a jury of the county of Northumberland.

BLACKSTONE (Sir William), an eminent English lawyer, was born at London in July 1723. His father, Mr Charles Blackstone, a silk-man, citizen, and bowyer of London, died some months before the birth of our author, who was the youngest of four children; and their mother died before he was 12 years old.

Even from his birth, the care both of his education and fortune was kindly undertaken by his maternal uncle Mr Thomas Bigg, an eminent surgeon in London, and afterwards, on the death of his elder brothers, owner of the Chilton estate, which is still enjoyed by that family. In 1730, being about seven years old, he was put to school at the Charter-house; and in 1735 was, by the nomination of Sir Robert Walpole, on the recommendation of Charles Wither of Hall in Hampshire, Esq; his cousin by the mother's side, admitted upon the foundation there. In this excellent seminary he applied himself to every branch of youthful education, with the same assiduity which

Blackstone.

Blackstone.

accompanied his studies through life. His talents and industry rendered him the favourite of his masters, who encouraged and assisted him with the utmost attention: so that at the age of 15 he was at the head of the school, and although so young, was thought well qualified to be removed to the university. He was accordingly entered a commoner at Pembroke college in Oxford, on the 30th of November 1738, and was the next day matriculated. At this time he was elected to one of the Charter-house exhibitions by the governors of that foundation, to commence from the Michaelmas preceding; but was permitted to continue a scholar there till after the 12th of December, being the anniversary commemoration of the founder, to give him an opportunity of speaking the customary oration which he had prepared, and which did him much credit. About this time also he obtained Mr Benfon's gold prize-medal of Milton, for verses on that poet. In the February following, the society of Pembroke college unanimously elected him to one of Lady Holford's exhibitions for Charter-house scholars in that house. Here he prosecuted his studies with unremitting ardour; and although the classics, and particularly the Greek and Roman poets, were his favourites, they did not entirely engross his attention: logic, mathematics, and the other sciences, were not neglected. At the early age of 20, he compiled a treatise entitled *Elements of Architecture*, intended for his own use only, and not for publication; but esteemed by those judges who have perused it, in no respect unworthy his maturer judgment and more exercised pen.

Having determined on his future plan of life, and made choice of the law for his profession, he was entered in the Middle Temple on the 20th of November 1741. He now found it necessary to quit the more amusing pursuits of his youth, for the severer studies to which he had dedicated himself; and betook himself seriously to reading law. He expressed his disagreeable sensations on this occasion in a copy of verses, since published by Doddsley in vol. 4th of his miscellanies, intitled *The Lawyer's Farewell to his Muse*; in which the struggle of his mind is expressed so strongly, so naturally, with such elegance of sense and language, and harmony of versification, as must convince every reader that his passion for the muses was too deeply rooted to be laid aside without much reluctance; and that, if he had pursued that flowery path, he would perhaps have proved inferior to few of our English poets.

Several little fugitive pieces besides this, have at times been communicated by him to his friends; and he left (but not with a view of publication) a small collection of juvenile pieces, both originals and translations, inscribed with this line from Horace,

Nec lassisse pudet, sed non incidere ludum.

Some notes on Shakespeare, which just before his death he communicated to Mr Steevens, and which were inserted by him in his last edition of that author, show how well he understood the meaning, as well as the beauties, of that his favourite among the English poets.

In November 1743, he was elected into the society of All-Souls college; and in the November following, he spoke the anniversary speech in commemoration of archbishop Chicheley the founder, and the other benefactors to that house of learning, and was admitted actual fellow.

From this period he divided his time between the university and the Temple, where he took chambers in order to attend the courts: in the former he pursued his academical studies, and on the 12th of June 1745 commenced bachelor of civil law; in the latter he applied himself closely to his profession, both in the hall and in his private studies, and on the 28th of November 1746 was called to the bar. Though he was little known or distinguished in Westminster-hall, he was actively employed, during his occasional residence at the university, in attending to its interests, and mingling with and improving its interior concerns.

In May 1749, as a small reward for his services, and to give him further opportunities of advancing the interests of the college, Mr Blackstone was appointed steward of their manors. And in the same year, on the resignation of his uncle Seymour Richmond, Esq; he was elected recorder of the borough of Wallingford in Berkshire, and received the king's approbation on the 30th of May.

The 26th of April 1750, he commenced doctor of civil law, and thereby became a member of the convocation, which enabled him to extend his views beyond the narrow circle of his own society, to the general benefit of the university at large.

In the summer 1753, he took the resolution of wholly retiring to his fellowship and an academical life, still continuing the practice of his profession as a provincial counsel.

His Lectures on the Laws of England appears to have been an early and favourite idea; for in the Michaelmas term, immediately after he quitted Westminster-hall, he entered on the province of reading them at Oxford; and we are told by the author of his life, that even at their commencement, such were the expectations formed from the acknowledged abilities of the lecturer, they were attended by a very crowded class of young men of the first families, characters, and hopes; but it was not till the year 1758, that the lectures in the form they now bear were read at the university.

Mr Viner having by his will left not only the copyright of his abridgment, but other property to a considerable amount, to the university of Oxford, to found a professorship, fellowships, and scholarships of common law, he was on the 20th of October 1758 unanimously elected Vinerian professor; and on the 25th of the same month read his first introductory lecture, which he published at the request of the vice-chancellor and heads of houses, and afterwards prefixed to the first volume of his Commentaries.

His lectures had now gained such universal applause, that he was requested by a noble personage who superintended the education of our present sovereign, then prince of Wales, to read them to his Royal Highness; but as he was at that time engaged to a numerous class of pupils in the university, he thought he could not, consistently with that engagement, comply with this request, and therefore declined it. But he transmitted copies of many of them for the perusal of his royal highness; who, far from being offended at an excuse grounded on so honourable a motive, was pleased to order a handsome gratuity to be presented to him.

It is doubtful whether the Commentaries were originally intended for the press; but many imperfect and incorrect copies having got abroad, and a pirated edition

edition of them being either published, or preparing for publication in Ireland, the learned lecturer thought proper to print a correct edition himself; and in November 1765 published the first volume, under the title of *Commentaries on the Laws of England*; and in the course of the four succeeding years, the remaining parts of this admirable work.

It ought to be remarked, that before this period the reputation his lectures deservedly acquired him had induced him to resume his practice in Westminster-hall; and in a course somewhat inverted from the general progress of his profession, he who had quitted the bar for an academic life, was sent back from the college to the bar, with a considerable increase of business. He was likewise elected into parliament, first for Hindon, and afterwards for Westbury in Wilts; but in neither of these departments did he equal the expectations his writings had raised.

The part he took in the Middlesex election drew upon him the attack of some persons of ability in the senate, and likewise a severe animadversion of one of the keenest polemical writers * in the paper-war of that day. This circumstance probably strengthened the aversion he professed to parliamentary attendance; "where, (he said) amidst the rage of contending parties, a man of moderation must expect to meet with no quarter from any side:" and when, on the resignation of Mr Dunning in 1770, he was offered the place of solicitor-general, he refused that office; but shortly afterwards, on the promotion of Sir Joseph Yates to a seat in the court of common-pleas, accepted a seat on the bench, and by the death of Sir Joseph succeeded him there also.

As a judge, he was not inactive; but, when not occupied in the duties of his station, was generally engaged in some scheme of public utility. The act for detached houses for hard labour for convicts, as a substitute for transportation, owed its origin in a great measure to him.

It ought not to be omitted, that the last augmentation of the judges salaries, calculated to make up the deficiencies occasioned by the heavy taxes they are subject to, and thereby render them more independent, was obtained in a great measure by his industry and attention. This respectable and valuable man died on the 14th of February 1780, in the 50th year of his age.

BIRCH, (Dr Thomas), an eminent historical and biographical writer, was born in London in 1705. His parents were both of them Quakers; and his father, Joseph Birch, was a coffee-mill maker by trade. Thomas being put to school, was indefatigable in his application, and stole many hours from sleep to increase his stock of knowledge. By this unremitting diligence, though he had not the happiness of an university education, he soon became qualified to take holy orders in the church of England, to the surprise of his acquaintance. In 1728 he married the daughter of the Rev. Mr Cox, to whom he was curate: but his felicity was of short duration, Mrs Birch dying of a puerperal fever in less than 12 months after their marriage; an event which he deploras in a very elegant and pathetic poem, preserved in Nichols's Collection. In 1732 he was recommended to the friendship and favour of the late lord high chancellor Hardwicke, then attorney-general; to which

noble peer, and to the present Earl of Hardwicke, he was indebted for all his preferments. The first proof he experienced of his patron's regard, was the living of Ulting in the county of Essex, in the gift of the crown, to which he was presented 1732. In 1734 he was appointed one of the domestic chaplains to the unfortunate Earl of Kilmarnock, who was beheaded 1746. Mr Birch was chosen a member of the Royal Society, Feb. 20. 1734-5; and of the Society of Antiquaries, Dec. 11. 1735, of which he afterwards became director till his death. Before this, the Marischal college of Aberdeen had conferred on him, by diploma, the degree of Master of Arts. In 1743, by the interest of Lord Hardwicke, he was presented by the crown to the sinecure rectory of Landewy Wel'rey in the county of Pembroke; and in 1743-4 was preferred, in the same manner, to the rectory of Sidington St Peter's, in the county and diocese of Gloucester. We find no traces of his having taken possession of this living; and indeed it is probable that he quitted it immediately for one more suitable to his inclinations and to his literary engagements, which required his almost constant residence in town; for on the 24th of February 1743-4, he was instituted to the united rectories of St Michael Woodstreet and St Mary Staining; and in 1745-6 to the united rectories of St Margaret Pattens and St Gabriel, Fenchurch-street, (by lord chancellor Hardwicke, in whose turn the presentation then was). In January 1752, he was elected one of the secretaries of the Royal Society, in the room of Dr Cromwell Mortimer, deceased. In January 1753 the Marischal College of Aberdeen created him doctor of divinity; and in that year the same degree was conferred on him by archbishop Herring. He was one of the trustees of the British Museum; for which honour he was probably indebted to the present Earl of Hardwicke, as he was for his last preferment, the rectory of Depden in Essex, to which he was inducted Feb. 26. 1761. In the latter part of his life he was chaplain to the princess Amelia. In 1765 he resigned his office of secretary to the Royal Society, and was succeeded by Dr Morton. His health declining about this time, he was ordered to ride for the recovery of it; but being a bad horseman, and going out Jan. 9. 1766, he was unfortunately thrown from his horse, on the road betwixt London and Hampstead, and died on the spot, in the 61st year of his age, to the great regret of the Doctor's numerous literary friends; and was buried in St Margaret Pattens. Dr Birch had in his lifetime been very generous to his relations; and none that were nearly allied to him being living at his decease, he bequeathed his library of books and manuscripts, with his picture painted in 1735, and all his other pictures and prints not otherwise disposed of by his will, to the British Museum. He likewise left the remainder of his fortune, which amounted to not much more than 5000, to be laid out in government-securities, for the purpose of applying the interest to increase the stipend of the three assistant librarians: thus manifesting at his death, as he hath done during his whole life, his respect for literature, and his desire to promote useful knowledge. To the Royal Society he bequeathed his picture painted by Wills in 1737, being the original of the mezzotinto print done by Fauber in 1741. His principal publications were, 1. "The General Dic-

Birch.

Birch,
Black.

tionary, Historical and Critical;" including a new translation of Mr Bayle, and interspersed with several thousand new lives. Dr Birch's associates in this undertaking were, the Rev. John Peter Bernard, Mr John Lockman, and Mr George Sale. The whole design was completed in 10 volumes folio. 2. Dr Cudworth's "Intellectual System" (improved from the Latin edition of Mosheim), his discourse on the true notion of the Lord's Supper, and two sermons, with an account of his life and writings, 2 vols 4to, 1743. 3. "The life of the Hon. Robert Boyle, 1744;" prefixed to an edition of that excellent philosopher's works, revised by Dr Birch. 4. "The lives of Illustrious Persons of Great Britain," annexed to the engravings of Houbraken and Vertue, 1747—1752. 5. "An Inquiry into the Share which King Charles I. had in the transactions of the Earl of Clarendon, 1747," 8vo. 6. An edition of "Spenser's Fairy Queen, 1751," 3 vols 4to, with prints from designs by Kent. 7. "The Miscellaneous Works of Sir Walter Raleigh;" to which was prefixed the Life of that great, unfortunate, and injured man, 1751, 2 vols 8vo. 8. "The Theological, Moral, Dramatic, and Poetical Works of Mrs Catherine Cockburn; with an Account of the Life of that very ingenious Lady, 1751," 2 vols 8vo. 9. "The Life of the Most Reverend Dr John Tillotson, Lord Archbishop of Canterbury. Compiled chiefly from his original Papers and Letters, 1752" 8vo. 10. "Milton's Prose Works, 1753," 2 vols 4to, with a new Life of that great Poet and Writer. 11. "Memoirs of the Reign of Queen Elizabeth, from the year 1581 till her death. In which the secret intrigues of her court, and the conduct of her favourite Robert Earl of Essex, both at home and abroad, are particularly illustrated. From the original papers of his intimate friend Anthony Bacon, Esq; and other manuscripts never before published, 1754," 2 vols 4to. 12. "The History of the Royal Society of London for improving natural knowledge, from its first rise. In which the most considerable of those papers, communicated to the Society, which have hitherto not been published, are inserted in their proper order, as a supplement to the Philosophical Transactions, 1756 and 1757. 4 vols 4to." 13. "The Life of Henry Prince of Wales, eldest Son of King James I. Compiled chiefly from his own papers and other manuscripts, never before published. 1760." 8vo. His numerous communications to the Royal Society may be seen in the Philosophical Transactions; and his poetical talents are evident from the verses already referred to.

BLACK-CAP, in ornithology, a species of *MOTACILLA*, under which article it was omitted to be described. It is a small bird, scarce weighing half an ounce. The crown of the head in the male is black; the hind part of the neck a light ash-colour: the back and coverts of the wings are of a greyish green: the quill-feathers and tail dusky, edged with dull green: the breast and upper part of the belly are of a pale ash-colour: the vent feathers whitish: the legs of a lead colour. The female is distinguished from the male by the spot on the head, which in that is of a dull rust-colour. The black-cap is a bird of passage, leaving us before winter. It sings very finely; and on that account is called in Norfolk the *mock-nightingale*.

Black,
Blackwall.

gale. It has usually a full, sweet, deep, loud wild pipe; yet the strain is of short continuance, and his motions are desultory: but when that bird sits calmly, and in earnest engages in song, he pours forth very sweet but inward melody; and expresses great variety of sweet and gentle modulations, superior perhaps to those of any of our warblers, the nightingale excepted.

The black-cap frequents orchards and gardens. Mr Pennant discovered the nest of this bird in a spruce fir, about two feet from the ground; the outside was composed of the dried stalks of the goose grass; with a little wool and green moss round the verge; the inside was lined with the fibres of roots, thinly covered with black horse hair. There were five eggs of a pale reddish brown, mottled with a deeper colour, and sprinkled with a few dark spots.

BLACK-JACK, a kind of mineral found in the Derbyshire mines. It was some time ago employed in Wales for mending the roads; but is now found to answer the purpose of calamine for making brass.—Monf. Van Swab, in 1738, was the first person who distilled zinc from Black-jack; and it is said that some English manufacturers purchased the secret from him when he was in England; though they might possibly have taken the hint from a work which he erected for the purpose above mentioned.

BLACKWALL, (Anthony, A. M.), a learned author, after completing his academical education at Emanuel college, Cambridge, was appointed head master of the free school at Derby, and lecturer of All-hallows there, where he first distinguished himself in the literary world by an edition of *Tueognis*, printed at London in 1706, and was afterwards head master of the free school at Market-Bosworth in Leicestershire. The Grammar whereby he initiated the youth under his care into Latin, was of his own composing, and so happily fitted for the purpose, that he was prevailed on to make it public, though his modesty would not permit him to fix his name to it, because he would not be thought to prefer to other instructors of youth. It is intitled, "A New Latin Grammar; being a short, clear, and easy Introduction of young Scholars to the Knowledge of the Latin Tongue; containing an exact Account of the two first Parts of Grammar." In his "Introduction to the Classics," first published in 1718, 12mo, he displayed the beauties of those admirable writers of antiquity, to the understanding and imitation even of common capacities; and that in so concise and clear a manner, as seemed peculiar to himself. But his greatest and most celebrated work was, "The Sacred Classics defended and illustrated; or, An Essay humbly offered towards preserving the Purity, Propriety, and True Eloquence of the Writers of the New Testament," in 2 vols. Mr Blackwall had the felicity to bring up many excellent scholars in his seminaries at Derby and Bosworth; among others, the celebrated Richard Dawes, author of the *Miscellanea Critica*. A gentleman who had been his scholar, being patron of the church of Clapham in Surrey, presented him to that living as a mark of his gratitude and esteem. This happening late in life, and Blackwall having occasion to wait upon the bishop of the diocese, he was somewhat pertly questioned by a young chaplain as to the extent of his learning. "Boy, (replied the indignant veteran), I have forgot more than ever you knew!"

BLEEDING. For chap. i. read n° 356. et seq.

BLOOD, last line of n° 27. for bringtons read lime-stones.

Mr Brown has made a number of experiments on solutions of the different metals precipitated by alkalis impregnated with the phlogiston of blood, as in the making of Prussian blue. This lixivium being poured into a solution of silver in aquafortis, produces a coagulum of a pure flesh-colour. The like lixivium made with flesh instead of blood, produces, in this case, a white coagulum; and simple oil of tartar being used in the same experiment, by way of comparison with these lixivia, afforded a much whiter sediment. Spirit of salt being added severally to all the three mixtures, the bloom of the flesh-colour was taken off in the first; but it suffered no other change. In the second, the coagulum was tinged a little blue; and in the third, the whiteness was evidently improved. The bluish tinge in the second case is not wholly to be attributed to the flesh; but perhaps might be owing to an alloy of copper in the silver, from which it is seldom entirely freed.

The same liquors were made use of to form a precipitate from corrosive sublimate of mercury dissolved in water: the consequence of which was, that the lixivium with the blood produced a pure yellow; that with flesh, an orange colour; and the simple oil of tartar, a dingy red. The addition of spirit of salt afterwards to these made some very odd alterations; for the first changed its yellow into an orange colour, and the second its orange colour to a blue, while the third became without any colour. The blue colour in the lixivium with the flesh, when mixed with this solution, may be accounted for from the vitriol in this preparation; but it is not so easy to say, why the same vitriol should not have produced also a blue in a lixivium with blood.

Copper, when dissolved in aquafortis, makes the water of a green colour; and on pouring to this the two lixivia of blood and of flesh, the coagula are much alike; that is, they are white, tinged with green; but on adding spirit of salt to them, they become of a colour not unlike that of copper before the solution. Oil of tartar gives a pale green solution; and the spirit of salt clears up the liquor, and restores it to its former colour.

Bismuth dissolved in aquafortis, and mixed with a lixivium of blood, produces a milky coagulum, which, after a short time standing, with the addition of some spirit of salt, becomes of a pale blue. The lixivium of flesh, and of crude salt of tartar, produced both white coagula, when the spirit of salt made no alteration in. From these experiments it appears, that not any of these metallic bodies would produce a fine blue colour with the lixivium of the blood; but a solution of iron answers all the experiments that are made with the solution of vitriol, and produces as fine a blue colour as that made in the common way.

BLUE JOHN, among miners, a kind of mineral which has lately been fabricated into vases and other ornamental figures. It is of the same quality with the cubical spar, with respect to its fusibility in the fire. It loses its colour, and becomes white in a moderate

heat: the weight of a cubic foot of the bluest kind is 3180 ounces, and that of the least blue is 3140 ounces. This substance began first to be applied to use about 18 years ago at one of the oldest mines in Derbyshire, called *Odin* mine, probably from its being dedicated to *Odin* the great god of the northern nations, at the foot of a high mountain called *Mam-Tor* in Castleton. Here the greatest quantities are still found; the largest pieces are sold for 9l. a ton, the middle-sized for 6l. and the least for 50s.

BLUSHING, a suffusion or redness of the cheeks, excited by a sense of shame, on account of consciousness of some failing or imperfection.

Blushing is supposed to be produced from a kind of consent or sympathy between several parts of the body, occasioned by the same nerve being extended to them all. Thus the fifth pair of nerves being branched from the brain to the eye, ear, muscles of the lips, cheeks, palate, tongue, and nose; a thing seen or heard that is shameful affects the cheeks with blushes, driving the blood into the minute vessels thereof; at the same time that it affects the eye and ear. For the same reason it is, as Mr Derham observes, that a savoury thing seen or smelt affects the glands and parts of the mouth; if a thing heard be pleasing, it affects the muscles of the face with laughter; if melancholy, it exerts itself on the glands of the eyes, and occasions weeping, &c. And to the same cause Dr Willis ascribes the pleasure of kissing.

BOILING FOUNTAIN. See ICELAND, and Plate CLVII.

BONITO, in ornithology. See SCOMBER, (*Encycl.*)

BOLETUS, (*Encycl.*) Horned cattle are fond of the brown boletus, and eat it greedily; but it is believed that it vitiates the milk, and lessens the quantity of it.

BONES, (*Encycl.*) From a discovery made by Mr Scheele, of a method of producing the phosphoric acid in large quantity from bones, it has been asserted, that this acid is naturally contained in the bones, united with a calcareous earth. From many experiments, however, it appears that no acid is naturally contained in calcined bones; nor can the acid of phosphorus be extracted from them but by means of the vitriolic acid: whence it seems probable, that the phosphoric acid in this case is produced by the combination of a certain quantity of earth with the vitriolic acid.—With regard to the earth of bones itself, it appears to be very different from the calcareous kind: it is much more soluble in the vitriolic acid, and may be precipitated from that or any other by means of the caustic volatile alkali, which cannot be done with the calcareous earth.

BOTANICAL TABLE, (*Encycl.*) In this table it was omitted to mark with their proper numbers, as proposed, the genera included in the 58 Orders belonging to Linnaeus's Fragments of a Natural Method of Classification. In the following recapitulation of those genera, that omission is supplied; the figures added to each genus denoting the natural order to which it belongs: and these numbers or figures may be marked with the pen at the corresponding genera in the Table itself.

 Bowyer.

BOTTS, (*Encycl.*) See also OESTRUS, (*Encycl.* and *Appendix.*)

BOW-LEGGED. See VALGUS, (*Encycl.*)

BOWYER (William), the most learned printer of his age, was born at White Fryars in London, Dec. 17. 1699. His father, whose name also was William, had been eminent in the same profession; and his maternal grandfather (Icabod Dawks) was employed in printing the celebrated Polyglott bible of bishop Walton. At a proper age, he was placed for grammatical education under the care of Mr Ambrose Bonwicke, a nonjuring clergyman of known piety and learning, who then lived at Headly, near Leatherhead in Surry. Here Mr Bowyer made great advances in literature, and a firm attachment commenced betwixt him and his master. On the 30th of January 1713, the whole property of the elder Mr Bowyer was destroyed by fire; on which occasion Mr Bonwicke generously undertook the education of his pupil for one year. In 1716, young Mr Bowyer was admitted a sizar at St John's college, Cambridge, where Dr Robert Jenkin was at that time master. He continued at the college of Cambridge under the tuition of the reverend Dr John Newcome till June 1722, during which period he probably took his degree of Bachelor of Arts; and it appears that he was desirous of obtaining a fellowship, though it is not certain that he ever stood a candidate for that honour. Soon after this he had an opportunity of repaying the kindness which Mr Bonwicke had shewn him, by officiating some time after his death in the capacity of a schoolmaster for the benefit of his family.

Mr Bowyer now entered into the printing-business along with his father. One of the first books which received the benefit of his correction was the complete edition of Selden in three volumes folio by Dr David Wilkins. This edition was begun in 1722, and finished in 1726; and Mr Bowyer's great attention to it appeared in his drawing up an epitome of Selden's *Synedriis*, as he read the proof-sheets. In 1727, he drew up an excellent sketch of William Baxter's Glossary of the Roman Antiquities. This was called "A view of a book intitled *Reliquie Baxterianæ*. In a letter to a friend." A single sheet 8vo. By this first public proof of Mr Bowyer's abilities, Dr Wotton and Mr Clarke were highly pleased; but as it was never published, and very few copies printed, it is very seldom found with the glossary.

In 1727 Mr Bowyer lost his mother; on which occasion he received a letter of consolation from Mr Chifhull the learned editor of the *Antiquitates Asiaticæ*. In October 1728 he married Miss Ann Prudom, his mother's niece, a very accomplished lady, by whom he had two sons, William and Thomas; the former of whom died an infant, and the latter survived his father. In 1729 Mr Bowyer published a curious treatise, intitled, "A Pattern for young Students in the Uni-

Uni-

Bowyer. University; set forth in the Life of Ambrose Bowditch, some time scholar of St John's College, Cambridge:" but though this treatise was generally ascribed to Mr Bowyer, it was in reality the production of Mr Ambrose Bowditch the elder. About this time it appears, that Mr Bowyer had written a pamphlet against the Separatists, though neither the title nor the occasion of it are now remembered. The same year, through the friendship of the Right Hon. Arthur Onslow, he was appointed printer of the Votes of the House of Commons; which office he held, under three successive speakers, for near 50 years.

In 1731 Mr Bowyer published, and, it is believed, translated, Voltaire's Life of Charles XII. This year also his wife died; on which occasion his friends Mr Clarke and Mr Chisholm wrote him very affectionate and Christian letters. He remained a widower till 1747, when he married; a very benevolent and worthy woman, Mrs Elizabeth Bill, by whom he had no children. In 1733 he published a piece in two sheets 4to, intitled, "The Beau and the Academic;" being a translation from a Latin poem recited that year at the Sheldonian theatre; and in 1736 he was admitted into the Society of Antiquarians, where he became an active and useful member.

In 1737 Mr Bowyer lost his father; and on this occasion Mr Clarke again addressed to him a letter of consolation. In 1742 our author published a translation of Trapp's Latin Lectures on Poetry, in which he was assisted by Mr Clarke, though the latter had a contemptible opinion of the performance.

In 1749, Mr Bowyer, along with Dr Burton, was virulently attacked by Dr King in a piece intitled *Elogium sancti inserviens Jacci Etoneusis five Gigantis*: or, "The praises of Jack Eaton, commonly called Jack the Giant."—This abuse was probably occasioned by Mr Bowyer's having hinted in conversation some doubts concerning the Doctor's skill in Latin. Our author drew up some strictures in his own defence, which he intended to insert at the conclusion of a preface to Montaigne's Reflections; but by Dr Clarke's advice they were omitted. In 1750, a prefatory critical dissertation and some notes were annexed by our author to Kuster's Treatise *De usu verborum mediæ ævæ*; a new edition of which, with farther improvements, appeared in 1773. He wrote likewise about the same time a Latin preface to Leedes's *Veteres poetæ citati*, &c.—Being soon after employed to print an edition of Col. Bladen's translation of Cæsar's Commentaries, that work received considerable improvements from Mr Bowyer's hands, with the addition of such notes in it as are signed TYROGA. In the subsequent editions of this work, though printed by another person during our author's lifetime, the same signature, though contrary to decorum, and even to justice, was still retained. In 1751, he wrote a long preface to Montaigne's "Reflections on the rise and fall of the Roman Empire;" translated the dialogue between Sylla and Socrates; made several corrections to the work from the Baron's "Spirit of Laws;" and improved it with his own notes. A new edition, with many new notes, was printed in 1759. In 1751 he also published the first translation that ever was made of Rousseau's paradoxical oration, which gained the prize at the academy of Dijon in 1750; and which first announced that singu-

lar genius to the attention and admiration of Europe. On the publication of the third edition of Lord Orrery's "Remarks on the Life and Writings of Dr Swift," in 1752, Mr Bowyer wrote and printed, but never published, "Two Letters from Dr Bentley in the Shades below, to Lord Orrery in a Land of thick darkness." The notes signed B, in the ninth quarto volume of Swift's works, are extracted from these Letters. In 1753, he endeavoured to allay the ferment occasioned by the Jew bill; with which view he published, in quarto, "Remarks on the speech made in common-council, on the bill for permitting persons professing the Jewish religion to be naturalized, so far as prophecies are supposed to be affected by it." This little tract was written with spirit, and well received by those who were superior to narrow prejudices. Its design was to show, that whatever political reasons might be alleged against the bill, Christianity was in no danger of being prejudiced by the intended protection promised to the Jews. The same year some of Mr Bowyer's notes were annexed to Bishop Clayton's translation of "A Journal from Grand Cairo to Mount Sinai and back again."—In 1754, Mr Bowyer, with a view of lessening his fatigue, entered into partnership with a relation; but some disagreement arising, the connection was dissolved in three years. On the death of Mr Richardson in 1761, Mr Bowyer succeeded him as printer to the Royal Society, through the favour of the late Earl of Macclesfield; and, under the friendship of five successive presidents, enjoyed that office till his death.

In 1763, Mr Bowyer published an excellent edition of the Greek Testament, in two vols 12mo. It appeared under the following title: *Novum Testamentum Græcum; ad fidem Græcorum solum Codicum MSS. nunc primum impressum, adjuvantibus Joanne Jacobo Wettsteno, juxta Sôlutiones J. Alberti Bengelii dicijum; et nova interpretatione sæpius illustratum. Accessere in altero volumine, Emendationes conjecturales virorum doctissimorum undecunque collectæ.* This fold with great rapidity: the Conjectural Emendations were well received by the learned, and are thought to be a valuable work. The president and fellows of Harvard college in Cambridge expressed their approbation of this edition in very high terms. In a letter to Mr Bowyer, written in the year 1767, "This work, (say they), though small in bulk, we esteem as a rich treasure of sacred learning, and of more value than many large volumes of the commentators." A second edition of the Conjectures on the New Testament, with very considerable enlargements, was separately published, in one vol. 8vo, in 1772. Bishop Warburton having censured a passage in the former edition, Mr Bowyer sent him a copy of this book, with a conciliatory letter. Dr Warburton's Divine Legation had received very considerable advantage from Mr Bowyer's corrections; and this even in an edition which was necessarily given to another press. In 1761 he was employed to print his Lordship's Doctrine of Grace. A second edition being soon wanted, and Mr Bowyer not having been intrusted with the care of it, he prepared a series of letters to the bishop in his own defence; of which, together with a few he had formerly received from that great writer, he afterwards printed twelve copies, of which ten have since been destroyed. However, there

is the best authority for asserting, that notwithstanding any little alterations which happened, Dr Warburton always retained a sincere regard for our author.

In 1765, at the request of Thomas Hollis, Esq; Mr Bowyer wrote a short Latin preface to Dr Wallis's *Grammatica Lingue Anglicanae*. He wrote also a larger English preface for the same work, which, however, still remains unprinted. In 1766 he entered into partnership with Mr Nichols, who had been trained by him to the profession, and had for several years assisted him in the management of his business. The same year, Mr Bowyer wrote an excellent Latin preface to *Joannis Harduini, Jesuitæ, ad Censuram Scriptorum veterum Prolegomena. Juxta Autographum*. In 1767 he was appointed to print the Journals of the House of Lords and the Rolls of Parliament. This year he printed Mr Clarke's excellent and learned work on "The Connection of the Roman, Saxon, and English Coins;" and wrote some notes upon it, which are interperfed throughout the volume with those of the author. Part of the Dissertation on the Roman seltence was likewise Mr Bowyer's production; and the index, which is an uncommonly good one, was drawn up by him entirely.

In January 1771 Mr Bowyer lost his second wife, and again received a letter of consolation from his old friend Mr Clarke, who had sent him one almost forty years before on a similar occasion. In the Philosophical Transactions for this year was printed a very ingenious "Inquiry into the Value of the ancient Greek and Roman Money," by the late Matthew Raper, Esq. But his opinions not coinciding with those of Mr Bowyer, he printed a small pamphlet, intitled, "Remarks, occasioned by a late Dissertation on the Greek and Roman money."

In 1773 three little tracts were published by him, under the title of "Select Discourses. 1. Of the correspondence of the Hebrew months with the Julian, from the Latin of Professor Michaelis. 2. Of the Sabbatical years, from the same. 3. Of the years of jubilee, from an anonymous writer in *Maillon's Histoire Critique de la Republique des Lettres*." In 1774 he corrected a new edition of Schrevelius's Greek Lexicon; to which he has added a number of words, distinguished by an asterisk, which he himself had collected in the course of his studies. Considerable additions, still in manuscript, were made by him to the lexicons of Hederic and Buxtorf, the Latin ones of Faber and Littleton, and the English Dictionary of Bailey; and he left behind him many other proofs of his critical skill in the learned languages. In 1774 was published, "The Origin of Printing, in two Essays. 1. The substance of Dr Middleton's Dissertation on the Origin of Printing in England. 2. Mr Meerman's Account of the Invention of the Art at Haerlem, and its progress to Mentz, with occasional Remarks, and an Appendix." The original idea of this valuable tract, was Mr Bowyer's, but it was completed by Mr Nichols.

Although our author, during the last ten years of his life had been afflicted with the palsy and stone, he not only preserved a remarkable cheerfulness of temper, but was enabled to support the labour of almost incessant reading; and he regularly corrected the learned works, especially the Greek books, which came

from his press. This he continued to do till within a few weeks of his death, which happened in November 1777, when he had nearly completed his 78th year.

For more than half a century Mr Bowyer was unrivalled as a learned printer; and many of the most masterly productions of this kingdom have come from his press. To his literary and professional abilities he added an excellent moral character; and he was particularly distinguished by his inflexible probity, and an uncommon alacrity in relieving the necessitous.

BRAMINS, (*Encycl.*) See also OBSERVATORY, (*Encycl.*)

TO BREAM, to burn off the filth, such as grafs, ooze, shells, or sea-weed, from a ship's bottom, that has gathered to it in a voyage, or by lying long in a harbour. This operation is performed by holding kindled furze, faggots, or such materials, to the bottom, so that the flame incorporating with the pitch, sulphur, &c. that had formerly covered it, immediately loosens and throws off whatever filth may have adhered to the planks. After this, the bottom is covered anew with a composition of sulphur, tallow, &c. which not only makes it smooth and slippery, so as to divide the fluid more readily, but also poisons and destroys those worms which eat through the planks in the course of a voyage. Breaming may be performed either when the ship lies aground after the tide has ebbed from her, or by docking, or by careening.

BRITAIN, (*Encycl.*) No 454, for *Antigallican privateer*, read the *Active* and *Favourite king's ships*.

BROWN (Dr John), a clergyman of the church of England, and an ingenious writer, was born at Rothbury in Northumberland in November 1715. His father John Brown, was a native of Scotland, of the Browns of Colstown near Haddington; and at the time of his son's birth was curate to Dr Thomlinson rector of Rothbury. He was afterwards collated to the vicarage of Wigton in Cumberland; to which place he carried his son, who received the first part of his education there. Thence he was removed, in 1732, to the university of Cambridge, and entered of St John's college, under the tuition of Dr Tunstall. After taking the degree of bachelor of arts with great reputation (being amongst the list of wranglers, and his name at the head of the list) he returned to Wigton, and received both deacon's and priest's orders from Sir George Fleming bishop of Carlisle. Here he was appointed by the dean and chapter a minor canon and lecturer of the cathedral church. For some years he lived here in obscurity; and nothing farther is known concerning him, than that in 1739 he went to Cambridge to take his degree of master of arts. In 1745 he distinguished himself as a volunteer in the king's service, and behaved with great intrepidity at the siege of Carlisle. After the defeat of the rebels, when several of them were tried at the assizes held at Carlisle in the summer of 1746, he preached at the cathedral church of that city two excellent discourses, on the mutual connection between religious truth and civil freedom; and between superstition, tyranny, irreligion, and licentiousness.

Mr Brown's attachment to the royal cause and to the Whig party procured him the friendship of Dr Ombaldston, who was the only person that continued to

BRAMINS
Brown.

be his friend through life, the peculiarities of Mr Brown's temper, or some other cause, having produced quarrels with every one else. When Dr Osbaldeston was advanced to the see of Carlisle, he appointed Mr Brown to be one of his chaplains.

It was probably in the early part of his life, and during his residence at Carlisle, that Mr Brown wrote his poem intitled *Honour*, inscribed to the Lord Viscount Londale. Our author's next poetical production was his *Essay on Satire*; and which was of considerable advantage to him both in point of fame and fortune. It was addressed to Dr Warburton; to whom it was so acceptable, that he took Mr Brown into his friendship, and introduced him to Ralph Allen, Esq; of Prior Park, near Bath, who behaved to him with great generosity, and at whose house he resided for some time.

In 1751 Mr Brown published his "Essays on the Characteristics of Lord Shaftesbury, &c." dedicated to Ralph Allen, Esq. This was received with a high degree of applause, though several persons attempted to answer it. In 1754, our author was promoted by the earl of Hardwicke to the living of Great Horkeley in Essex.

In 1755, our author took the degree of Doctor of Divinity at Cambridge. This year he published his tragedy of *Barbarossa*; which, under the management of Mr Garrick, was acted with considerable applause; but when it came to be published, it was exposed to a variety of strictures and censures. This tragedy introduced our author to the acquaintance of that eminent actor; by whose favour he had a second tragedy, named *Athelstan*, represented at Drury-Lane play-house. This was also well received by the public; but did not become so popular as *Barbarossa*, nor did it preserve so long the possession of the stage.

In 1757 appeared his famous "Estimate of the manners and Principles of the Times." The reception which this work met with from the public was very flattering to his vanity; no fewer than seven editions of it having been printed in little more than a year. The chief design of this performance was to show, that a vain, luxurious, and selfish effeminacy in the higher ranks of life marked the character of the age; and to point out the effects and sources of this effeminacy. Several antagonists appeared, some of whom were neither destitute of learning nor ingenuity; though Mr Brown himself asserted that Dr Wallace, a clergyman of Edinburgh, was the only candid and decent adversary that appeared against him. The testimony given by M. de Voltaire to the effect which the Estimate had on the conduct of the nation, is very honourable to Dr Brown. "When Marshal Richlieu, in 1756, (says that celebrated writer) laid siege to Port Mahon, the capital of Minorca, the British sent out admiral Byng with a strong naval force, to drive the French fleet off the island, and raise the siege. At this time there appeared a book, entitled *An Estimate of the Manners of the Times*; of which there was no less than five editions printed off in London in the space of three months. In this treatise the author proves that the English nation was entirely degenerated;—that it was near its ruin;—that its inhabitants were no longer so robust and hardy as in former times;—and that its soldiers had lost their courage. —This work roused the sensibility of the English na-

tion, and produced the following consequences. They attacked, almost at one and the same time, all the sea-coasts of France, and her possessions in Asia, Africa, and America." In 1758, our author published the second volume of his *Estimate of the Manners and Principles of the Times*; containing additional remarks on the ruling manners and principles, and on the public effects of those manners and principles. The design of this volume was, to retract such mistakes as he thought he had committed; to prove such points as were affirmed and not proved; to illustrate those particulars which were hinted, but not explained; to reply to such capital objections as had been made to his general system by preceding writers on the same subject; and to display the consequences which might be fairly deduced from his principles, and through a designed brevity were omitted in the first volume. But it unfortunately happened that the Doctor's self-opinion, which gave so much offence in his first volume, broke out in the second with still greater violence. The consequence of this was, that he exposed himself to general censure and dislike; and the prejudices against him occasioned the real excellencies of the work to be very much overlooked. The periodical critics, whom he had gone needlessly out of his way to abuse, treated him with uncommon severity; and such a multitude of antagonists rose against him, so many objections were urged upon him, by friends as well as enemies, that he seems to have been deeply impressed, and to have retired for a while into the country. From the country it was that he wrote, in a series of letters to a noble friend, "An Explanatory Defence of the Estimate of the Manners and Principles of the Times; being an Appendix to that Work, occasioned by the Clamorous lately raised against it among certain Ranks of Men."

But while Dr Brown thus distinguished himself as a political writer, he was advanced to no higher dignity in the church; nay, on some disgust, it is supposed, he resigned his living in Essex; however, in recompence, Dr Osbaldeston procured him the rectory of St Nicholas in Newcastle on Tyne. He would probably have received further favours from this prelate, had not the latter died soon after his promotion to the see of London.

In 1760 our author published an Additional Dialogue of the Dead, between Pericles and Aristides; being a sequel to a dialogue of Lord Lyttelton's between Pericles and Cosmo. One design of this additional dialogue was to vindicate the measures of Mr Pitt, against whose administration Lord Lyttelton had been supposed to have thrown out some hints. Our author's next publication, in 1763, was "The cure of Saul," a sacred ode; which was followed in the same year by "A Dissertation on the Rise, Union, and Power, the Progressions, Separations, and Corruptions of Poetry and Music." This is one of the most pleasing of Dr Brown's performances, and abounds with a variety of critical discussions. A number of strictures on this piece were published; and the Doctor defended himself in a treatise intitled *Remarks on some Observations on Dr Brown's Dissertations on Poetry and Music*. In 1764 our author published, in octavo, "The History of the Rise and Progress of Poetry through its several Species;" which is no more than the substance given in the dissertation abovementioned. The same year Dr Brown published

list of a volume of sermons, dedicated to his patron Dr Osbaldeston bishop of London; but most, if not all of these, had been separately published, excepting the first three, which were on the subject of education. In the beginning of the year 1765, the Doctor again returned to politics, and published "Thoughts on Civil Liberty, Licentiousness, and Faction." At the conclusion of this work the author prefaced a code of education, upon which Dr Priestley made remarks at the end of his "Essay on the Course of a Liberal Education for civil and active Life." The same year he published a sermon "On the Female Character and Education," preached on the 16th of May, 1765, before the guardians of the asylum for deserted female orphans. His last publication was, in 1766, "A Letter to the Rev. Dr Lowth, occasioned by his late Letter to the Right Reverend Author of the Divine Legation of Moses." This was occasioned by Dr Lowth's having clearly, though indirectly, pointed at Dr Brown as one of the extravagant adulators and defenders of bishop Warburton. Besides these works, Dr Brown published a poem on Liberty, and two or three anonymous pamphlets. At the end of several of his later writings, he advertised his design of publishing "Christian Principles of Legislation," but was prevented from executing it by his death; though the work appears to have been completed.

We come now to the concluding events of our author's life; concerning which the following is the most authentic intelligence that can be procured. Whilst Dr Dumarsq resided in Russia in the year 1765, to which he had been invited the preceding year to give his advice and assistance for the establishment and regulation of several schools which her Imperial majesty intended to erect, he received a letter from a lady of distinguished character in England, recommending to him Dr Brown as a proper correspondent on this occasion. Dr Dumarsq then wrote a letter to Dr Brown, telling him the occasion of his application, and the difficulties that occurred. He had imagined that nothing more would be wanted of him than what concerned classical learning, and a general foundation for the sciences; as that had been the common introduction to every kind of useful knowledge in the western parts of Europe. But on his arrival he found that a much more extensive scheme was required; and such as extended not only to learning properly so called, but also to matters military and naval, civil and commercial. But having stated his difficulties in executing this plan to Dr Brown, the latter proposed a scheme still more extensive; and which was no less than a general plan of civilization throughout the whole Russian empire. In this plan, however, though it showed very enlarged ideas and great strength of mind, there were several defects which rendered it, as Dr Brown himself was afterwards convinced, impracticable. He had laid greater stress upon the support, energy, and efficacy of absolute power in princes when exerted in a good cause, than experience would warrant; and he was ready to imagine that the bulk of the Russian nation, just emerging out of barbarism, was like a *tabula rasa*, upon which any characters might be written. At last the Doctor's letter was laid before the empress, who was so pleased with it that she immediately invited him to Russia. He accepted the invitation, and

procured his Majesty's leave to go: 1000 l. were ordered for his expence, and he actually received 200 l. But when he was on the point of setting out, an attack of the gout and rheumatism, to which he had been all his lifetime subject, so impaired his health, that his friends dissuaded, and at last succeeded in preventing him from going. The money was returned, excepting 97 l. 6 s. which had been expended in necessaries for the intended journey. But though he thus declined the journey, a long letter which he afterwards wrote to the empress, and which does honour to his abilities, shows that he had not abandoned his intention of being serviceable. The affair, however, taken in all its circumstances, did no doubt greatly agitate his mind; and his being obliged at length to give up the journey, must have been no small disappointment to a man of his sanguine expectations. This disappointment concurring with the general state of his health, and perhaps the recollection of some other failures that had happened, was followed by a dejection of spirits; in consequence of which he put an end to his life on the 23d of September 1766, in the 51st year of his age. On the morning of that day his servant came into his bed-chamber, and asked him what fort of a night he had had? to which he replied, "A pretty good one." The servant having quitted the bedside for a few minutes, heard a noise in the Doctor's throat, which he imagined to be owing to some obstruction occasioned by phlegm. Going to assist his master, he found him speechless, and bleeding profusely, having cut the jugular vein with a razor; and this he had done so effectually, that death speedily ensued. Such was the unhappy end of this ingenious writer; but the manner of it, when some previous circumstances of his life are understood, will call no stain on his character. He had a tendency to insanity in his constitution; and from his early life, had been subject at times to some disorder in his brain, at least to melancholy in its excess. Mrs Gilpin of Carlisle, soon after Dr Brown's decease, wrote in the following terms in a letter to a friend. "His distemper was a frenzy, to which he had by fits been long subject; to my own knowledge, above 30 years. Had it not been for Mr Farish frequently, and once for myself, the same event would have happened to him long ago. It was no premeditated purpose in him; for he abhorred the thought of self-murder; and in bitterness of soul expressed his fears to me, that one time or another some ready mischief might present itself to him, at a time when he was wholly deprived of his reason."

BRUCHUS, (*Encyel.*) See Plate CCCXIII.

BUBONOCELE. For n° 13. read p. 8388, 8422.

BUG, (*Encyel.*) Early in the spring, even in February, the larva of these creatures begins to burst from the egg; and it is at this season that attention is so very requisite. The bed ought to be stripped of all its furniture; which should be washed, and even boiled, if linen; if stuff, it should be hot-pressed. The bedstead should be taken to pieces, dusted, and washed with spirit of wine in the joints; for in those parts the females lay their eggs. This done, the joints, crevices, cavities, &c. should be well filled with the best soft soap mixed with verdigrise and Scots snuff. On this substance the larva, if any escape the cleaning, or

Bursera
||
Calcareous.

any, which is common in old houses, creep into the bedstead, will feed at first, and of course be destroyed: this last will effect the purpose in houses where these vermin are not so numerous, by repeating the operation every three months.—Professor Kalm † mentions, that from repeated trials, he has been convinced that sulphur, if it be properly employed, entirely destroys bugs and their eggs in beds or walls, though they were ten times more numerous than the ants on an ant-hill. His translator, Dr. Forster, adds, that a still more effectual remedy is, to wash all the infected furniture with a solution of arsenic. See further the article CIMICIFUGA, below.

BURSERA, in botany, a genus of the monogynia order, belonging to the hexandria class of plants. There is but one species, the gummifera, or gum-clim. This is a large tree. The leaves are pennate, the middle rib five or six inches long, with the pinne set opposite to one another on footstalks half an inch long. The blossoms

are succeeded by purple-coloured berries bigger than large peas, hanging in clusters on a stalk of about five inches long, to which each berry is joined by a foot-stalk of half an inch long. The seed is hard, white, and of a triangular figure, inclosed within a thin capsule, which divides in three parts, and discharges the seed. This tree produces a large quantity of gum, of a brown colour, and of the consistence of turpentine. It is esteemed a good vulnerary, and is much used for horses. Most of the Bahama islands abound with these trees.

BUTTERWORT, (*Encycl.*) Wherever this plant, called also *Yorkshire fanicle*, is found, it is a certain indication of a boggy soil. It has long had the reputation of being noxious to sheep. The country people believe that it gives them the rot whenever they eat it, which they will not do but from great necessity. Hence this plant has been called the *white rot*.

C.

CABBAGE BARK-TREE. See GEOFFRÆA, below.

CABINDA, the chief port of the kingdom of Angoy in Loango in Africa. It is situated at the mouth of a river of the same name about five leagues north of Cape Palmerino, on the north side of the mouth of the river Zaire. The bay is very commodious for trade, wooding, and watering.

CACHEXY. For *Index subjoined to Medicine*, read, p. 4810.

CACTUS. For CERES, read CEREUS.

CÆSARIAN OPERATION. For chap. vi. read chap. xv.

CALAMUS, in botany, a genus of the monogynia order, belonging to the hexandria class of plants. There is but one species, the rotang, or true Indian cane. The stem is without branches, has a crown at top, and is every where beset with straight spines. This is the true Indian cane, which is not visible on the outside; but the bark being taken off discovers the smooth stick, which has no marks of spine on the bark, and is exactly like those which the Dutch sell to us; keeping this matter very secret, lest travellers going by should take as many canes out of the woods as they please. Sumatra is said to be the place where most of these sticks grow. Such are to be chosen as are of a proper growth between two joints, suitable to the fashionable length of canes as they are then worn: but such are scarce.

CALASH. For n° 76. read n° 73.

CALCAREOUS EARTH, (*Encycl.*) Though this kind of earth cannot be vitrified by itself in the heat of our common furnaces, it is remarkable, that by mixing it with argillaceous earth, which is as unvitrescible as itself, both will melt together into glass. To illustrate this, Dr. Watson relates the following experiment. "Mix well together equal weights of powdered chalk or other calcareous body, and powdered pipe-clay; put the mixture into a crucible. Any where towards the middle of the crucible put two solid pieces; one of pure chalk, the other of pure clay, so that they may not be contiguous to each

other, but be every where severally surrounded with the mixture of chalk and clay. Then by exposing the whole to a strong degree of heat for a sufficient length of time, it will be found that the mixture has been converted into glass; and upon breaking the vitrified mass, we shall discover the two solid pieces of chalk and clay unvitrescified and unaltered in their figure, tho' every where surrounded with glass.

It is remarkable, that some kinds of calcareous earth, after being deprived of all their fixed air by calcination, will regain, upon being exposed to the atmosphere, the very same quantity that they lost, while others will not. Dr. Watson informs us, that having calcined into lime 204 grains of dove marble, the lime weighed whilst hot 116 grains. This was done on the 6th of March; and on the 5th of November following it weighed 203½ grains. As it had been frequently weighed during that interval, it is very probable that the half grain had been lost by repeating this operation. A second experiment torned out, as accurately as could be expected, the same. Some dry chalk, weighing 120 grains, was reduced by calcination to 68. This quantity of lime increased only to 104 grains; so that 16 parts in 120, or between one seventh and one eighth of its weight, were never regained. The Doctor gives a reason for this defect of increase in the following manner. "The chalk or clunch (says he) of this country, is not a pure calcareous earth, but contains a portion of sand: and hence, when a definite weight of this chalk-lime is exposed to the air, it cannot acquire as much increase of weight as the same quantity of purer lime would do; for the sand which is mixed with the lime is of a very different nature from it, and does not attract any thing from the air." It is difficult, however, on this supposition, to see why the sand should lose any thing by calcination; for as it can regain no air, so it can lose none in the fire. The following is a table of the weight regained by lime made from different materials, according to Dr. Watson's experiments. He observes, however, that there is great reason to believe, that the quantity of matter which

Batter.
||
Calcareous.

† Travels in
America.

the same sort of lime can attract from the air, depends very much on the degree of heat with which the lime has been burned. There is a certain definite degree of heat requisite to make the lime attract the greatest possible quantity from the air. When the heat is not sufficient to convert the whole of the substance into lime, then that part which is not converted into lime will not contribute any thing to the increase of the lime when exposed to the air, inasmuch as it possesses no quality of attracting any thing from the air. Our author observes also, that the same effect takes place when the heat has been more than sufficient to convert the whole of the substance into lime; for then a partial vitrification takes place. The following substances were changed into lime by being exposed to a very fierce fire for 24 hours. The experiment was made in November 1779; and in three months they had all acquired the greatest increase of weight. The first column of the table expresses the increase of weight which a ton of the same substances gained; and the second expresses that which they would have gained, had they been exposed to the fire only for four hours.

CALCINATION, (Encycl.) In confirmation of the opinion that the increase of weight in metallic calces is owing to the adhesion of elastic fluids, it may be observed, that various metallic calces are in great measure soluble in water; which shows that they have something of a saline nature. Perhaps the elastic, or that matter, whatever it is, which generates the elastic fluids obtained from these calces, renders them so.

CALX ANTIMONII, is the earthy part of the regulus of antimony when deprived of its phlogiston. See **PHARMACY**, no 791. By the mere action of fire, however, the whole of its phlogiston cannot be dissipated; though it may be done by the addition of nitre, and the calx become perfectly white; but in this case it cannot be melted into glass, except in the focus of a burning mirror. The calx of antimony, perfectly deprived of its phlogiston, has been used in medicine chiefly under the name of *diaphoretic antimony*; but little regard is now paid to it.

CAMPHORA. In marginal note, for no 198. read *The Table*.

CAMPVEER. See **VEER**, (Encycl.)

Lighting a CANDLE by a small spark of electricity. This method, which is an invention of Dr Ingenhousz, is recorded in the Phil. Trans. vol. 68. It is done by a small vial, having eight or ten inches of metallic coating, or even less, charged with electricity, which may be done at any time of the night by a person who has an electric machine in his room. "When I have occasion to light a candle," says he, "I charge a small-coated phial, whose knob is bent outwards, so as to hang a little over the body of the phial; then I wrap some loose cotton over the extremity of a long brass pin or a wire, so as to stick moderately fast to

its substance. I next roll this extremity of the pin wrapped up with cotton in some fine powder of resin, (which I always keep in readiness upon the table for this purpose, either in a wide-mouthed phial or in a loose paper); this being done, I apply the extremity of the pin or wire to the external coating of the charged phial, and bring, as quickly as possible, the other extremity wrapped round with cotton to the knob: the powder of resin takes fire, and communicates its flame to the cotton, and both together burn long enough to light a candle. As I do not want more than half a minute to light my candle in this way, I find it a readier method than kindling it by flint and steel, or calling a servant.

"I have found, that powder of white or yellow resin lights easier than that of brown.

"The *farina lycopodii* may be used for the same purpose: but it is not so good as the powder of resin, because it does not take fire quite so readily, requiring a stronger spark not to mis; besides, it is soon burnt away.

"By dipping the cotton in oil of turpentine, the same effect may be as readily obtained, if you take a jar somewhat greater in size. This oil will inflame so much the readier if you threw a few fine particles of brags upon it. The pin dust is the best for this purpose; but as this oil is scattered about by the explosion, and when kindled fills the room with much more smoke than the powder of resin, I prefer the last."

CANDLE-BOMBS, a name given to small glass bubbles, having a neck about an inch long, with a very slender bore, by means of which a small quantity of water is introduced into them, and the orifice afterwards closed up. This stalk being put through the wick of a burning candle, the vicinity of the flame soon rarifies the water into steam, by the elasticity of which the glass is broken with a loud crack.

CANELLA ALBA, (Encycl.) Marginal note, for no 201, read *Catalogue of Simple, (Encycl.)* See also **WINTERANIA** in this Appendix.

CANNEL COAL, a species of coal remarkable for being easily kindled, and burning with a bright flame. It receives its name from *canewyll*, which in the old British language signifies "a candle;" the want of which is supplied by the bright flame of this coal. See **COAL**, (Encycl.)

CANTHARIS, (Encycl.) The cantharis poscillus, which is frequently found in pastures and under juniper trees, shines by night. In Italy and North America a species of winged cantharides remain all night on the shrubs and branches of trees, emitting light; but on the approach of any enemy instantly fly off, and the whole tree seems on fire. This wonderful light, which has no connection either with the culinary or electric fire, is placed in the segments of the abdomen of the insect while it remains alive.

CAOUTCHOUC, (Encycl.) A method of dissolving this elastic gum without ether is as follows: Take one pound of the spirit of turpentine, and a pound of the gum cut into very small pieces; pour the turpentine into a long-necked matras, which must be placed in a sand-bath; throw in the gum, not all at once, but by little and little according as it is perceived to dissolve. When it is entirely dissolved, pour into the matras a pint of nut or linseed oil, or oil of pop-

Candle
Caoutchouc

pices,

CARDAMOM *||* **Chefelden.** pies, rendered delicate in the usual manner with litharge. Then let the whole boil for a quarter of an hour, and the preparation is finished.—This would make an excellent varnish for Air-balloons; were it not so expensive on account of the price of the gum.

CHESELDEN, (William), an eminent anatomist and surgeon, was born at Burrow on the Hill, in the

county of Leicester, descended from an ancient family in the county of Rutland, whose arms and pedigree are in Wright's "History of Rutland." He received the rudiments of his professional skill at Leicester; and married Deborah Knight, a citizen's daughter, by whom he had one daughter, Williamina Deborah. In 1713 he published his *Anatomy of the Human Body*, 1 vol. 8vo; and in 1723, *A Treatise on the high Operation for the Stone*. He was one of the earliest of his profession who contributed by his writings to raise it to its present eminence. The following verses were addressed to him in 1733, "on his many dextrous and successful operations:"

Oh wondrous Artificer (surely given,
By the peculiar grace of Heaven,
As a new Saviour to mankind,
The lame to cure, relieve the blind,
And, by the ever happy knife,
To ease, and lengthen human life!
How dost thou grace that noble art,
Which owes to you its noblest part!
How well deserve the general praise
Your universal fame does raise!
How just your merit, for the place
Conferred on you by royal grace!
Well might the care alone be thine,
To tend on gracious Caroline,
Since all allow your skill divine.
No more let France her artificers boast,
To you but smatterers at most.
Their Charité, or Hôpital Dieu,
Ne'er saw such cures as done by you;
Aware of this, with utmost speed,
Their New ACADEMY decreed
You all their honours, and, to grace
Their list, therein give you a place:
From such a member they receive
A greater honour than they give.
Long may you live, and bless the land
With your unerring skill and hand,
May this ne'er fail, that never wane;
And may they both defend to Sharn!

In the beginning of 1736, he was thus honourably mentioned by Mr Pope: "As soon as I had sent my last letter, I received a most kind one from you, expressing great pain for my late illness at Mr Chesheldens. I conclude you was eased of that friendly apprehension in a few days after you had dispatched yours, for mine must have reached you then. I wondered a little at your quære, who Chesheldens was. It shews that the truest merit does not travel so far any way as on the wings of poetry: he is the most noted and most deserving man in the whole profession of chirurgery; and has saved the lives of thousands by his manner of cutting for the stone." He appears to have been on terms of the most intimate friendship with Mr Pope, who, frequently, in his Letters to Mr Richardson, talks of dining with Mr Chesheldens, who then lived in or near Queen Square. In February 1737, Mr Chesheldens was appointed surgeon to Chelsea Hospital. As a governor of the Foundling Hospital, he sent a benefaction of 50l. to that charity, May 7. 1751. inclosed in a paper with the following lines:

'Tis what the happy to the unhappy owe;
For what man gives, the gods by him bestow.

POPE.
He died at Bath, April 11. 1752, of a disorder arising from drinking ale after eating hot buns. Finding himself uneasy, he sent for a physician, who advised vomiting immediately; and if the advice had been taken,

taken, it was thought his life might have been saved. By his direction, he was buried at Chelief.

CHEVERON. For n° 23, 24. read p. 3592.

CHINA, (*Encycl.*) The immense population of China, recorded under that article, n° 55. falls very far short of that recorded by some late authors. In the *Memoirs of the History, &c.* of the Chinese by the missionaries at Pekin, published at Paris in 1780, we find a controversy on this subject between M. Pau and the ex-jesuit M. Amiot. The former had published a book, intitled "Philosophical Inquiries concerning the Egyptians and Chinese," in which he rates the population of China much below 82 millions. Amiot is so far from being of this opinion, that he estimates their number at 200 millions. To confirm this estimate, he produces a list made in 1743, of all that paid taxes in the respective provinces, that is, of all the heads of families; and, on summing up their numbers, he finds 28,516,428 families; in which enumeration, says he, women, children, and domestics, are not reckoned. The Chinese reckon, at an average, six to a family; M. Amiot reduces this computation to five, and on this supposition makes the inhabitants of China amount to 142,582,400 souls. But in this number the Missionary comprehends neither the grand mandarins, the inferior ones, nor the literati, nor the military, which amount, according to his calculations, to upwards of seven millions; which added to the enumeration abovementioned, make 149,663,000 souls. Fifty millions are nevertheless still wanting to make up the 200 millions at which our Missionary estimates the inhabitants of China. These he finds in the inhabitants of Pekin, which he reckons at two millions, the Mantcheou Tartars, who live among the Chinese, the tradesmen, the persons employed in the silk manufactures, and the populace of the cities, which are not registered. But the computations of M. Amiot are liable to great difficulties, and are certainly arbitrary and uncertain in several respects. He comprehends in his enumeration districts and provinces that belong to Tartary, and not to China; and he calculates often from registers of the same districts, that are discordant and contradictory. When it is considered, that the enumerations of the inhabitants of China have been different under different dynasties, as all the emperors did not possess the same extent of territory,—that the wars with the Tartars often obliging the Chinese to withdraw in great numbers towards the south, rendered certain provinces more populous at one period than they were at another,—that the numbers of the poor, the straggling labourers, and of those that ply on the rivers, cannot be easily computed,—and that many of the registers are evidently arbitrary; we find ourselves disposed to suspend our determination of the controversy between M. Amiot and M. Pau relative to the object now under consideration. If population had gone on increasing in China, from the third century before the Christian era (which was the period of their rising power), the Chinese might have sent into Tartary numerous colonies, which would have peopled that country and civilized its inhabitants. But this has not been the case; and notwithstanding all the pious relations of the Missionaries, it is certain, that a bad administration,—the extortions and oppressive conduct of civil and military officers,—the revolutions occa-

sioned by the establishment of different dynasties,—famine,—epidemics,—inundations,—wars,—massacres,—and the fall of great ministers, involving their friends and families in ruin, keep population within certain bounds, and hinder it from rising to a pitch that would produce new and fatal revolutions.

CHITAU. For *Lignum-aloes*, read *Xylo-aloes*.

CHIVALRY, (*Encycl.*) See also KNIGHT, (*Encycl.*)

CHOCOLATE, (*Encycl.*) This, according to Linnæus, is more salutary than either tea or coffee. There are three methods of preparing it, as practised by the Indians, the Spaniards, and others. The Indians, to one pound of the roasted nuts put half a pound of sugar dissolved in rose-water, and half a pound of flour of maize or Indian corn. The Spaniards, to six pounds of the nut add three and an half of sugar, seven pods of vanillas, one pound and an half of Indian corn, half a pound of cinnamon, six cloves; one drachm of capsicum, and whatsoever is thought requisite of the rouscou nut to improve the colour, together with ambergrise or mullk to give an agreeable scent. In the other and more common way, to seventeen pounds of nuts are added ten pounds of sugar, twenty-eight pods of vanillas, one drachm of ambergrise, and six ounces of cinnamon.

CICINDELA, (*Encycl.*) See also Glow-Worm, (*Encycl.*)

CIMICIFUGA, in botany, a genus of the polyandria order, belonging to the diœcia class of plants. Mæsserschmidius, in the *Isis Siberica*, gives it the following character and name: *Cimicifuga fistida* with the leaves of the herb Christopher, bearing a thyrsus of yellow male flowers with a red villous seed, the seed-vessel in form of a horn. This whole plant to resembles the *actæa racemosa*, that it is difficult to distinguish them when not in flower; but in the fructification it greatly differs from it, the *cimicifuga* having four pistills, the *actæa* but one. Jacquin says, that it is a native of the Carpathian mountains. It has obtained the name of *cimicifuga*, or *bugbane*, both in Siberia and Tartary, from its property of driving away those insects; and the botanists of those parts of Europe which are infested by them, have long desired to naturalise it in their several countries.

COAL, (*Encycl.*) See also PITCH and TAR, (*Encycl.*)

CAPE COAST, the name of the chief British settlement on the coast of Guinea in Africa. The name is thought to be a corruption of *Cabo Corso*, the ancient Portuguese appellation. This cape is formed by an angular point, washed on the south and east by the sea, on which stands the English fort. Here the Portuguese settled in 1610, and built the citadel of Cape Coast upon a large rock that projects into the sea. A few years afterwards they were dislodged by the Dutch, to whom this place is principally indebted for its strength. In 1664 it was demolished by Admiral Holmes,

Cobalt
||
Coccus.

Holmes, and in 1665 the famous Dutch admiral De Ruyter was ordered by the states to revenge the insults of the English. With a squadron of 13 men of war he attacked all the English settlements along the coast, ruined the factories, took, burnt, and sunk all the shipping of the English Company: however, after all his efforts, he was baffled in his attempts on Cape Coast. By the treaty of Breda it was confirmed to the English, and the king granted a new charter in 1672; on which the Company applied all their attention to the fortifying and rendering it commodious.

COBALT. At the end, for *Zaffre*, read *Regulus*.

COCCINELLA, (*Encycl.*) Dele the whole article, and read as follows:

COCCINELLA, a genus of insects of the order of coleoptera; the characters of which are these: The antennæ are subelavated; the palpi are longer than the antennæ, the last articulation heart-shaped; the body is hemispheric; the thorax and elytra are margined; the abdomen is flat. This genus is divided into sections, from the colour of the elytra, and of the spots with which they are adorned. The females, impregnated by the males, deposit their eggs, which turn to small larvæ, flow in their progress, and enemies to the plant-louse. Those larvæ are frequently found upon leaves of trees covered with plant-lice. On the point of being metamorphosed, they settle on a leaf by the hinder part of their body, then bend and swell themselves, forming a kind of hook. The skin extends, grows hard; and in a fortnight's time the chrysalis opens along the back. The insect in its perfect state receives the impressions of the air, that gives its elytra a greater degree of consistence. It seldom flies, and cannot keep long on the wing. Of all the different larvæ of the coccinella, the most curious is the white hedgehog, a name given it by M. de Reaumur on account of the singularity of its figure, and the tufts of hair which render it remarkable. It seeks its food on the leaves of trees. After a fortnight, it settles on one spot, and, without parting with its fur, turns to a chrysalis; three weeks after which, it becomes a coccinella. The slough appears nowise impaired by its transformation. M. de Reaumur has observed it on a plum-tree. It is likewise found upon the rose-tree.

When the coccinellæ first arrive at the state of perfection, the colours of their elytra are very pale, nearly bordering upon white or cream colour; and the elytra are very soft and tender, but soon grow hard, and change to very lively brilliant colours. Their eggs are of an oblong form, and of the colour of amber.

The cochineal-insect, described by mistake under this title in the *Encyclopædia*, belongs to a different genus. See *Coccus*, below.

COCCUS, the COCHINEAL, was by mistake confounded with the COCCINELLA, (*Encycl.*) which is a genus belonging to a different order. See COCCINELLA, above.

After "frequent," line 6th of the article *Coccus*, in *Encycl.* supply as follows.

The most remarkable species are:

1. The *coccus hesperidum*, or green-house bug, is oval, oblong, of a brown colour, covered with a kind of varnish: It has six legs; with a notch and four bristles at the tail. It infests orange-trees, and other similar plants in green-houses. When young, it runs

upon the trees; but afterwards fixes on some leaf, where it hatches an infinity of eggs, and dies. The male is a very small fly.

2. The *coccus phalaridis*. The male of this cochineal is small. Its antennæ are long for its size. The feet and body are of a reddish colour, nearly pink, and sprinkled with a little white powder. Its two wings, and the four threads of its tail, are snow white, and of those threads two are longer than the rest. It is to be found upon the species of gramin which Linnæus calls *phalaris*. The female contrives, along the stalks of that dog-grass, little nests, of a white cottony substance, in which she deposits her eggs. The small threads of her tail are scarce perceptible.

3. The *coccus casti*, or famous Mexican cochineal, (see COCHINEAL, below), a native of the warm parts of America. In Mexico this species is nursed with great care. It naturally fixes upon the leaves of various kinds of plants. The Indians gather them, put 10 or 12 into little beds made of mofs or of the flue of coco; after which they hang them upon the thorns of the plant known under the various names of *racket*, *cardassia*, *Indian fig-tree*, *opuntia*, *nopal*. There grow great quantities of that plant round their habitations. The gall-insects give birth to myriads of young ones. They disperse, feed on the juice of the plant, and there produce a fresh generation. There are three gatherings of them every year. The first is performed by taking off the nests brought and placed upon the plants; the second, by loosening the cochineal from off the leaves with pincers; and the third, at the approach of winter, by cutting off the leaves that are yet loaded with the insects. Those plants remaining green for a considerable time, afford them sustenance. When they have attained their full size, they are taken off by scraping the leaf. This last cochineal is not of so fine a quality, because a little of the epiderm of the leaf is blended with it. The Spaniards call it *granilla*. As soon as the insects are brought together, they are destroyed. The method taken to effect this has great influence upon the colour. It then goes by various names. That which they kill by the gentle heat of ovens, is of an ash-grey or mottled, and is named *jafpeada*. If the insects are deprived of life by plunging them with baskets into hot water, it then goes by the appellation of *renegrida*, which is not covered over with a white powder. Lastly, it bears the name of *negra*, if destroyed upon the hot plates that have been used for roasting of maize. By this last process it sometimes receives too great a degree of heat, from which it turns somewhat black. Three pounds of fresh-gathered cochineals weigh but one when dried. The cochineal thus nursed upon cultivated plants, yields a more beautiful colour, and in greater quantity, than does the wild. Dried cochineals will preserve their colouring particles for ages, as no other insect fixes on them; neither do they ever decay. This valuable insect is used for dyeing, where it produces a red colour of an excellent tincture, in variety of shades. It is made into scarlet and crimson. The English mix it with gum-lac to dye their cloths. This dye is more expeditious, as good, and cheaper. The cochineal furnishes painters with the most lively colours and most beautiful shades; and the same substance, ground and prepared, produces carmine, which, skilfully laid on over

Coccus.

Plate
COCXIII.

Plate
COCXIII.

the ladies cheeks, emulates nature. At Constantinople they sell a crape or very fine lawn dyed in cochineal; and the same is imitated at Straburgh. This lawn, dipped in water, may be used equally with the macarato-wool of Portugal to the same purposes as cochineal, one of which is to give a colour to liquors. It is computed that there are imported yearly into Europe, in the course of trade, 880,000 pounds of cochineals.

The female cochineal had been long known, and well described, by several naturalists; but the male having been seldom seen, the history of this valuable insect has hitherto been very defective. Mr Ellis, being informed that this insect bred in great abundance on the cactus opuntia of Linnaeus, in South Carolina and Georgia, as well as on the cactus coccinifer in Mexico and Jamaica, obtained from Dr Garden some branches of the former, with the insects upon them. In examining several of these specimens, he at last discovered three or four minute dead flies with white wings; and having moistened them in spirit of wine, and observing them with a microscope, found that they were of a bright red colour, which convinced him that these were the true male insects. Dr Garden, to whom this discovery was communicated, made several observations on the male species. This is very rarely found; so that he imagines there may be 150 or 200 females for one male. The male is much less than the female, more active, and better made; and the body of it is of a lighter red than that of the other.

4. The coccus ilicis, or that forming the kermes grains, inhabits the quercus coccifera of the southern parts of Europe. Mr Hellot of the French Academy of Sciences, in his Art of Dyeing, chap. 12. says it is found in the woods of Vauvert, Vendeman, and Narbonne; but more abundantly in Spain, towards Alicante and Valencia. It not only abounds in Valencia, but also in Murcia, Jaen, Cordova, Seville, Estremadura, la Mancha, Serranias de Cuenca, and other places.

In Xixona and Tierra de Rellu, there is a district called *De la Grana*, where the people of Valencia first began to gather it, whose example was followed all over Spain. It has some years produced 30,000 dollars (5000 l.) to the inhabitants of Xixona.

Both ancients and moderns seem to have had very confused notions concerning the origin and nature of the kermes; some considering it as a fruit, without a just knowledge of the tree which produced it; others taking it for an excrescence formed by the puncture of a particular fly, the same as the common gall observed upon oaks. Tournefort was of this number. Count Marfigli, and Dr Nisole a physician of Montpellier, made experiments and observations, with a view of further discoveries; but did not perfectly succeed. Two other physicians at Aix in Provence, Dr Emeric and Dr Garidel, applied themselves about the same time, and with greater success; having finally discovered that the kermes is in reality nothing else but the body of an insect transformed into a grain, berry, or husk, according to the course of nature.

The progress of this transformation must be considered at three different seasons. In the first stage, at the beginning of March, an animalcule, no larger than a grain of millet, scarce able to crawl, is perceived sticking to the branches of the tree, where it fixes itself, and soon becomes immoveable; at this period it

grows the most, appears to swell and thrive with the sustenance it draws in by degrees. This state of rest seems to have deceived the curious observer, it then resembling an excrescence of the bark; during this period of its growth, it appears to be covered with a down, extending over its whole frame like a net, and adhering to the bark: its figure is convex, not unlike a small floe; in such parts as are not quite hidden by this soft garment, many bright specks are perceived of a gold colour, as well as stripes running across the body from one space to another.

At the second stage, in April, its growth is completed, its shape is then round, and about the size of a pea: it has then acquired more strength, and its down is changed into dust, and seems to be nothing but a husk or a capsule, full of a reddish juice not unlike discoloured blood.

Its third state is towards the end of May, a little sooner or later, according to the warmth of the climate. The husk appears replete with small eggs, less than the seed of a poppy. These are properly ranged under the belly of the insect, progressively placed in the nest of down that covers its body, which it withdraws in proportion to the number of eggs: after this work is performed, it soon dies, though it still adheres to its position, rendering a further service to its progeny, and shielding them from the inclemency of the weather, or the hostile attacks of an enemy. In a good season they multiply exceedingly, having from 1800 to 2000 eggs, which produce the same number of animalcules. When observed with the microscope in July or August, we find, that what appeared as dust, are so many eggs or open capsules, as white as snow, out of each of which issues a gold-coloured animalcule, of the shape of a cockroach, with two horns, six feet, and a forked tail.

In Languedoc and Provence the poor are employed to gather the kermes, the women letting their nails grow for that purpose, in order to pick them off with greater facility.

The custom of lopping off the boughs is very injudicious, as by this means they destroy the next year's harvest. Some women will gather two or three pounds a-day; the great point being to know the places where they are most likely to be found in any quantity, and to gather them early with the morning-dew, as the leaves are more pliable and tender at that time, than after they have been dried and parched by the rays of the sun: strong dews will occasionally make them fall from the trees sooner than usual: when the proper season passes, they fall off of themselves, and become food for birds, particularly doves. Sometimes there will be a second production, which is commonly of a less size with a fainter tinge. The first is generally found adhering to the bark, as well as on the branches and stalks; the second is principally on the leaves, as the worms choose that part where the nutritious juice preserves itself the longest, is most abundant, and can be most easily devoured in the short time that remains of their existence, the bark being then drier and harder than the leaves.

Those who buy the kermes to send to foreign parts spread it on linen, taking care to sprinkle it with vinegar, to kill the worms that are within, which produces a red dust, which in Spain is separated from the husk.

Coccus
Cockburne.

hulk. Then they let it dry, passing it through a sieve, and make it up into bags. In the middle of each, its proportion of red dust, put in a little leather bag, also belongs to the buyer; and then it is ready for exportation, being always in demand on the African coast.

The people of Hanojos, Bonares, Villalba, and other parts of the kingdom of Seville, dry it on mats in the sun, stirring it about, and separating the red dust, which is the finest part, and being mixed with vinegar goes by the name of *pasell*. The same is done with the barks; but these have but half the value of the dust.

The kermes of Spain is preferred on the coast of Barbary, on account of its goodness. The people of Tunis mix it with that of Tetuan, for dyeing those scarlet caps so much used in the Levant. The Tunisians export every year above 150,000 dozen of these caps, which yields to the Dey a revenue of 150,000 hard dollars (33,750 l.) *per annum* for duties; so that, exclusive of the uses and advantages of kermes in medicine, it appears to be a very valuable branch of commerce in Spain.

5. The coccus polonicus. See *Coccus Polonicus*, (Enceyl.)

COCHINEAL, or COCHENEEL, a drug used by the dyers, &c. for giving red colours, especially crimsons and scarlets, and for making carmine; and likewise in medicine as a cardiac, cordial, sudorific, alexipharmic, and febrifuge.

The cochineal, in the state in which it is brought to us, is in small bodies of an irregular figure, usually convex, and ridged and furrowed on one side, and concave on the other. The colour of the best is a purplish grey, powdered over with a sort of white dust. All that the world knew of it for a long time was, that it was gathered from certain plants in Mexico; and therefore it was naturally supposed to be a seed, till in the year 1692 Father Plumier gave Pomot an account of its being an animal. And this, though then disregarded, has been confirmed by subsequent observations. Indeed, to determine the point, we have now the means in our own hands, even in this part of the world.—We need only moisten and soak in water, or in vinegar, a number of cochineals till they are swelled and distended, to know that every one is the more or less perfect body of an insect; the most imperfect and mutilated specimens always show the rings of the body; and from observing others, it will be easy to find the number and disposition of the legs; parts, or even whole ones, being left on several, and often complete pairs. In this way the legs, antennæ, and proboscis, may be discovered. See *Coccus* above.

COCKBURN (Mrs Catharine), a most accomplished lady and celebrated writer, was the daughter of captain David Trotter, a native of Scotland, and a sea-commander in the reign of king Charles II. She was born in London, Aug. 16. 1679, and baptized in the Protestant church, according to which she was bred up in her infancy a Protestant; but being a sprightly, ingenious, and beautiful child, she was particularly caressed by some considerable families among the Papists. This favour naturally wrought a good opinion of such friends; and entering into an intimacy with them as she grew up, she became an easy conquest to

their faith, in which she continued many years. In the mean time her genius ripened apace, and shot forth proofs of her talents for poetry, even before she had passed her childhood. In her 17th year she produced a tragedy called *Agnes de Castro*, which was acted in 1695. This performance, and some verses addressed to Mr Congreve upon his *Mourning Bride* in 1697, brought her into the acquaintance of that gentleman. Thus encouraged in her first attempt, her Muse brought upon the stage three plays more, before the death of Mr Dryden in 1701, to whose memory she joined with several other ladies in paying a tribute of verse. However, poetry and dramatic writing was not the most distinguished of Mr's Trotter's talents; she had a remarkable philosophic turn, and capacity equal to such researches. Mr Locke's Essay on Human Understanding came out during this interval: that famous philosopher had dressed out logic and metaphysics in such a new mode as was very agreeable to the taste of the sex in general, and particularly engaged the attention and admiration of our young authoress. She had begun to project a defence of the essay against some remarks of Dr Burnet of the Charter-house, which was finished so early as the beginning of December 1701. She had but lately passed the 22d year of her age; and the mastery with in which the piece was drawn must needs have given singular pleasure to her great champion, who accordingly expressed his satisfaction by a present of books to his fair defendress. Philosophy sojourns in the neighbourhood of religion; these philosophic reveries would naturally lead a thoughtful mind to that subject; and taking into her consideration the tenets of her present faith, she began to discover their indefensible grounds: she therefore resolved to renounce it, and published a vindication of her change in 1707; and returning to the established church of Scotland, she changed her condition likewise the next year, 1708, and was married to Mr Cockburne, a learned divine of that church. The duties of a wife and mother called Mrs Cockburne from her books and pen many years; and domestic cares engaging her attention, we hear nothing of her as a writer till 1726, when her zeal for Mr Locke's opinions drew her again into public light. She exercised her pen afterwards as occasion offered; and in 1739 she entered into the controversy concerning the foundation of moral duty and obligation. In that controversy she wrote two treatises, the first of which she transmitted in manuscript to Mr afterwards Dr Warburton, the late bishop of Gloucester, who published it, with a preface of his own, in 1747. Mrs Cockburne survived this publication two years only. She died in 1749, and was interred at Long Horsley, near her husband, who died the year before her, with this short sentence upon the tomb, "Let their works praise them in the gates." Prov. xxx. 31. Her works were collected and published in 1751, in two volumes 8vo, with an account of her life prefixed.—This collection is an incontestible proof of the author's genius. But her abilities as a writer will not be seen without attending to the peculiar circumstances in which her writings were produced: her early youth, for instance, when she wrote some; her very advanced age, and ill state of health, when she drew up others; the uneasy situation of her fortune during

during the whole course of her life; and an interval of near 20 years, in the vigour of it, spent in the cares of a family, without the least leisure for reading or contemplation; after which, with a mind so long diverted and encumbered, refusing her studies, she instantly recovered its entire powers; and, in the hours of relaxation from domestic employments, pursued to the utmost limits some of the deepest researches the human understanding is capable of. Her character is that of a most uncommon lady, no less celebrated for her beauty in her younger years, than for her genius and accomplishments. She was small of stature, but had a remarkable liveliness in her eyes, and a delicacy of complexion which continued to her death.

COLLINSON (Peter), an eminent naturalist and antiquarian, descended of an ancient family, was born on the paternal estate called *Hugal-Hall*, or *Height of Hugal*, near Windermere lake, in the parish of Stavelay, about ten miles from Kendal in Westmoreland. Whilst a youth he discovered his attachment to natural history. He began early to make a collection of dried specimens of plants, and had access to the best gardens at that time in the neighbourhood of London. He became early acquainted with the most eminent naturalists of his time; the Drs Dérham, Woodward, Dale, Lloyd, and Sloane, were amongst his friends. Among the great variety of articles which form that superb collection, now (by the wife disposition of Sir Hans and the munificence of parliament) the British Museum, small was the number of those with whose history Mr Collinson was not well acquainted; he being one of those few who visited Sir Hans at all times familiarly; their inclinations and pursuits in respect to natural history being the same, a firm friendship had nearly been established between them. Peter Collinson was elected a fellow of the Royal Society on the 12th of December, 1728; and perhaps was one of the most diligent and useful members, not only in supplying them with many curious observations himself, but in promoting and preserving a most extensive correspondence with learned and ingenious foreigners, in all countries, and on every useful subject. Besides his attention to natural history, he minutely every striking hint that occurred either in reading or conversation; and from this source he derived much information, as there were very few men of learning and ingenuity who were not of his acquaintance at home; and most foreigners of eminence in natural history, or in arts and sciences, were recommended to his notice and friendship. His diligence and economy of time was such, that though he never appeared to be in a hurry, he maintained an extensive correspondence with great punctuality; acquainting the learned and ingenious in distant parts of the globe, with the discoveries and improvements in natural history in this country, and receiving the like information from the most eminent persons in almost every other. His correspondence

with the ingenious Cadwallader Colden, Esq; of New York, and the justly celebrated Dr Franklin of Philadelphia, furnish instances of the benefit resulting from his attention to all improvements. The latter of these gentlemen communicated his first essays on electricity to Mr Collinson, in a series of letters, which were then published, and have been reprinted in a late edition of the Doctor's ingenious discoveries and improvements. Perhaps, in some future period, the account procured of the management of sheep in Spain, published in the Gentleman's Magazine for May and June 1764, may not be considered among the least of the benefits accruing from his extensive and inquisitive correspondence. His conversation, cheerful and usefully entertaining, rendered his acquaintance much desired by those who had a relish for natural history, or were studious in cultivating rural improvements; and secured him the intimate friendship of some of the most eminent personages in this kingdom, as distinguished by their taste in planting and horticulture, as by their rank and dignity. He was the first who introduced the great variety of seeds and shrubs, which are now the principal ornaments of every garden; and it was owing to his indefatigable industry, that so many persons of the first distinction are now enabled to behold groves transplanted from the Western continent flourishing so luxuriantly in their several domains, as if they were already become indigenous to Britain. He had some correspondents in almost every nation in Europe, some in Asia, and even at Pekin; who all transmitted to him the most valuable seeds they could collect, in return for the treasures of America. The great Linnæus, during his residence in England, contracted an intimate friendship with Mr Collinson, which was reciprocally increased by a multitude of good offices, and continued to the last. Besides his attachment to natural history, he was very conversant in the antiquities of our own country, having been elected a member of the Society of Antiquaries April 7th, 1737; and he supplied them often with many curious articles of intelligence and observations, respecting both our own and other countries. He died in 1768, leaving behind him many materials for the improvement of natural history.

COLUBER NAJA, or *Cobra de Capello*, a very deadly kind of serpent in the East Indies. The root of the lignum colubrium (*ophiorrhiza*) is said to have been pointed out to the Indians as an antidote against the bite of this serpent by the viverra ichneumon, a creature which fights with this serpent, and cures itself by eating of this plant when wounded. The Indians, when bit, instantly chew it, swallow the juice, and apply the masticated root to the puncture.

COMPASS. For NAVIGATION, *Señ.* i. 15. read p. 5359, par. 15.

COMPASSES, PROPORTIONAL, are those whose joint lies between the points terminating each leg: Plate they are either *simple* or *compound*. In the former fort CCCXIII. the centre is fixed, so that one pair of these serves only for one proportion.

Compound proportional COMPASSES consist of two branches, each pointed at either end with steel: the length of the branches is cut through, for a cursor to slide up and down; in the middle of which cursor is a screw,

Collinson
Compass.

Compasses. screw, serving to join the branches, and to fix them at any point required. On the one leg are divisions, serving to divide lines into any number of equal parts, for reducing of figures, &c. On the other are numbers, for inscribing any regular polygon in a circle proposed.

The use of the first is easy. Suppose, *v. gr.* a right line required to be divided into three equal parts; push the cursor till the screw be just on the figure 3; where fixing it, take the length of the given line between the longest part of the legs: the distance between the two shortest will be one-third of the given line. In the same manner may the line be divided into any other number of parts.

For the use of the line of polygons. Suppose, *v. gr.* a pentagon required to be inscribed in a circle; push the cursor till the middle of the screw be against 5, the number of sides in a pentagon; between the shortest parts of the legs take the diameter of the circle: the legs thus opened, the distance between the points of the longest parts will be the side of the pentagon to be inscribed in the circle. And thus for a figure of any other number of sides.

Proportional COMPASSES with the sector lines. The structure of these is so like that of the common proportional compasses, only a little nicer, that it needs no particular description.

The lines on the first face are the line of lines, marked *lines*; it is divided into 100 equal parts, every tenth numbered; and the line of chords, which goes to 60°, is marked *chords*.

On the other face are a line of lines to 90°, and a line of tangents to 45°. On the other side are the tangents from 45° to 71° 34'; on the other, secants from 0° to 70° 30'.

For the use of these compasses. 1. To divide a line into any number of equal parts less than 100: Divide 100 by the number of parts required; slip the cursor till the line on the sliding dovetail be against the quotient on the line of lines; then, the whole line being taken between the points of the compasses most remote from the centre, the aperture of the other will show the division required. 2. A right line given, supposed to be divided into 100 parts, to take any number of those parts: slip the line on the sliding dovetail to the number of parts required; the whole line being taken between the points farthest from the centre, the aperture of the other two will include the number of divisions required. 3. The radius being given, to find the chord of any arch under 60°: slip the line on the sliding dovetail to the degrees required on the line of chords; the radius being taken between the points farthest from the centre of the cursor, the aperture of the other line will be the chord required, provided the number of degrees be greater than 29; if it be less, the aperture taken from the radius will leave the chord required. 4. If the chord of an arch under 60° be given, and the radius required; slip the line on the dovetail to the degrees given on the line of chords; the given chord being taken between the two points next the cursor, the aperture of the other will be the radius required. 5. The radius being given, to find the sine of any number of degrees: slip the line on the dovetail to the degree on the line of sines whose sine is required; the radius taken between the points fur-

thest from the cursor, the aperture of the other will give the sine of the angle required: but if the sine sought be less than 30°, the difference of the apertures of the opposite points will be the sine required. 6. The radius being given, to find the tangent of any number of degrees under 71: if the tangent required be under 26° 30', then slip the line on the dovetail to the degree proposed on the tangent line; the radius taken between the points farthest from the cursor, the aperture of the others will be the tangent of the degrees required: if the tangent required be above 26° 30', but under 45°, the line on the cursor must be slipped to the degrees given on the tangent line; then the radius being taken between the points furthest from the cursor, the aperture of the others will be the tangent. If the tangent required be greater than 45°, but less than 56° 20', slip the notch on the tangent side of the turned cheek to the degree 0 in the tangent line on the side of the compass; the radius taken between the points farthest from the cursor, the difference between the aperture of the other and these added together, will be the tangent required. Thus, for the tangents of other degrees under 71. After the like manner may the secant of any number of degrees under 71 be found.

Mr Heath, a mathematical-instrument maker in London, constructed a pair of proportional compasses in 1746, with a curious and useful contrivance for preventing the shorter legs from changing their position when these compasses were used. It consisted of a small beam foldered to a screw, and running parallel to the leg of the compasses, nearly of the length of the groove: in this beam a slit was made, which admitted of a sliding-nut, the other end of which fell into a hole in the bottom of the screw belonging to the great nut of the compasses. The screw-pin of the beam passed through an adjuster, by means of which the mark on the slider might be brought exactly to any division. But the *proportional compasses* have been much out of use since the invention of the sector.

COMPOSITION, (Encycl.) See also the articles **DIALOGUE, EPISTLE, and HISTORY, (Encycl.)**

COMUS, in mythology, the god of jollity or festivity. There is great reason to believe he was the Chamos of the Miabites; Beel-Phegor, Baal Peor, Priapus, and Bacchus. He is represented under the appearance of a young man, with an inflamed red countenance, his head inclined, and crowned with flowers; his air drowsy; leaning on a huntsman's spear in his left hand, and holding an inverted torch in his right. His statue was placed at the chamber doors of new married persons; his pedestal crowned with flowers.

CONCEPTION, in medicine, denotes the first formation of the embryo, or foetus, in the womb.

Conception is no other than such a concurrence and commixture of the prolific seed of the male with that of the female, in the cavity of the uterus, as immediately produces an embryo.

The symptoms of conception or pregnancy are, when, in a few days after the conjugal act, a small pain is perceived about the navel, and is attended with some gentle commotions in the bottom of the abdomen; and within one, two, three, or even four, months, the menses cease to flow, or prove in less quantity than usual. Upon the first failure of this kind,

Compass
Conception

kind, the woman begins to count the series of her weeks, without taking any notice of the time before elapsed; after this, or between the second or third months, but generally about the third, the motions of the embryo become perceivable to the mother; who hereupon becomes troubled with a nausea, vomiting, loathing, longing, &c. About this time the breasts begin to swell, grow hard and painful, and contain a little milk; the nipples also become larger, firmer, and darker coloured, a livid circle appearing round them: the eyes seem sunk and hollow. During the two first months of pregnancy, the woman grows thinner and slenderer; the abdomen being also depressed; though it afterwards distends, and grows gradually larger.

The manner wherein conception is effected is thus laid down by the modern writers. In the superficies of the ovaries of women, there are found little pellucid spherules, consisting of two concentric membranes filled with a lymphatic humour, and connected to the surface of the ovaria, underneath the tegument, by a thick calix, contiguous to the extremities of the minute ramifications of the Fallopian tubes.

These spherules, by the use of venery, grow, swell, raise and dilate the membrane of the ovary into the form of papillæ; till, the head propending from the stalk, it is at length separated from it; leaving behind it a hollow cicatrix in the broken membrane of the ovary; which, however, soon grows up again.

Now, in these spherules, while still adhering to the ovary, fetuses have been frequently found; whence it appears, that these are a kind of ova, or eggs, deriving their structure from the vessels of the ovary, and their liquor from the humours prepared therein.

Hence also it appears, that the Fallopian tubes being swelled and stiffened by the act of venery, with their muscular fibrillæ, like fingers, may embrace the ovaries, compress them, and by that compression expand their own mouths: and thus the eggs, now mature, and detached as before, may be forced into their cavities, and thence conveyed into the cavity of the uterus; where they may either be cherished and retained, as when they meet with the male seed; or, if they want that, again expelled.

Hence the phenomena of false conceptions, abortions, fetuses found in the cavity of the abdomen, the Fallopian tubes, &c. For in coition, the male-seed, abounding with living animalcules, agitated with a great force, a brisk heat, and probably with a great quantity of animal-spirits, is violently impelled through the mouth of the uterus, which on this occasion is opener, and through the valves of the neck of the uterus, which on this occasion are laxer than ordinary, into the uterus itself; which now, in like manner, becomes more active, turgid, hot, inflamed, and moistened with the flux of its lymph and spirits, by means of the titillation excited in the nervous papillæ by the attrition against the rugæ of the vagina.

The semen thus disposed in the uterus, is retained, heated, and agitated, by the convulsive constriction of the uterus itself; till meeting with the ova, the finest and most animated part enters through the dilated pores of the membranula of the ovum, now become glandulous; is there retained, nourished, dilated; grows to its umbilicus, or navel; stifles the other less lively animalcules; and thus is conception effected.

Hence it appears, that conception may happen in any part where the semen meets with an ovum: thus, whether it be carried through the Fallopian tube to the ovary, and there cast upon the ovum; or whether it meet with it in some recess of the tube itself; or, lastly, whether it join it in the cavity of the uterus, it may still have the same effect, as it appears from observation actually to have done. But it is probable, that conception is then most perfect when the two, viz. the semen and ovum, are carried at the same time into the uterus, and there mixed, &c.

Other anatomists choose to suppose the male-seed taken up, before it arrives in the uterus, by the veins which open into the vagina, &c. and thus mixed with the blood; by which, in the course of circulation, it is carried, duly prepared, into the ovary, to impregnate the eggs.

It has been advanced by several writers, that women may possibly conceive in their sleep, and be with child without any knowledge of the occasion of it. As ridiculous and absurd as this doctrine may appear to the generality of the world, no less an author than Geu-fili has thought it worthy a particular dissertation.

COOK (Captain James), a late celebrated navigator, was born at Marton, a village about four miles from Great Ayton, in the county of York, and christened there, as appears from the parish register, November 3. 1728. His father formerly used to be employed as a fisherman, and sometimes as a day-labourer; and his son divided his early life between the lowest duties in husbandry and the little school-learning which could be afforded him. He afterwards lived with a grocer in that country: but not liking his situation, he bound himself an apprentice to the master of a collier trading from Newcastle to London; with whom he might have continued, had not the want of seamen in the royal navy occasioned his removal into the service of his sovereign before the expiration of his indentures.

The time which intervened between this and his being raised to be a commission-officer, was not passed in such a manner as to render it worthy of any detail. He soon acquired all the requisites which belonged to his profession; and deported himself so much to the satisfaction of his superiors, that he received a commission as lieutenant on the first day of April 1760; and soon after gave a specimen of those abilities which recommended him to the commands which he executed so highly to his credit.

In the year 1765 he was with Sir William Burnaby on the Jamaica station; and that officer having occasion to lend dispatches to the governor of Jucatan, relative to the logwood cutters in the Bay of Honduras, lieutenant Cook was selected for that employment; and he performed it in a manner which intitled him to the approbation of the admiral. A relation of this voyage and journey was published in the year 1769, under the title of "Remarks on a Passage from the River Balise, in the Bay of Honduras, to Merida, the capital of the province of Jucatan in the Spanish West Indies, by Lieutenant Cook," in an 8vo pamphlet.

To a perfect knowledge of all the duties belonging to a sea-life, Mr Cook had added a great skill in astronomy. In the year 1767, the Royal Society resolved, that it would be proper to send persons into some part

of the South Seas, to observe the transit of the planet Venus over the sun's disk; and by a memorial delivered to his majesty, they recommended the islands of Marquesas de Mendoza, or those of Rotterdam or Amsterdam, as the properest place then known for making such observation. To this memorial a favourable answer was returned; and the Endeavour, a ship built for the coal-trade, was put in commission, and the command of her given to lieutenant Cook. But before the vessel was ready to sail, captain Wallis returned from his voyage, and pointed out Otaheite as a place more proper for the purpose of the expedition than either of those mentioned by the Royal Society. This alteration was approved of; and our navigator was appointed by that learned body, with Mr Charles Green, to observe the transit. On this occasion lieutenant Cook was promoted to be captain, and his commission bore date the 25th of May 1768. He immediately hoisted the pennant, and took command of the ship; in which he sailed down the river on the 30th of July. In this voyage he was accompanied by Joseph Banks, Esq; and Dr Solander; and on 12th June 1771 returned to England, after having been absent almost three years. The narrative of this expedition was written by Dr Hawkesworth.

Soon after captain Cook's return to England, it was resolved to equip two ships to complete the discovery of the southern hemisphere. It had long been a prevailing idea, that the unexplored part contained another continent. To ascertain the fact was the principal object of this expedition; and that nothing might be omitted that could tend to facilitate the enterprise, two ships were provided, furnished with every necessary which could promote the success of the undertaking. The first of these ships was called the Resolution, under the command of captain Cook; the other the Adventure, commanded by captain Furneaux. Both of them sailed from Deptford on the 9th of April 1772, and arrived at the Cape of Good Hope on the 30th of October. They departed from thence on the 22d of November; and from that time until the 17th of January 1773, continued endeavouring to discover the continent, when they were obliged to relinquish the design, observing the whole sea covered with ice from the direction of S. E. round by the south to west. They then proceeded into the South Seas, and made many other discoveries, and returned to the Cape of Good Hope on the 21st of March 1774, and from thence to England on the 14th of July; having, during three years and eighteen days (in which time the voyage was performed), lost but one man by sickness in captain Cook's ship; although he had navigated throughout all the climates from 52° north to 71° south, with a company of 118 men.

The relation of this voyage was given to the public by captain Cook himself, and by Mr George Forster, son of Dr Forster, who had been appointed by government to accompany him for the purpose of making observations on such natural productions as might be found in the course of the navigation. That published by captain Cook has generally been ascribed to a gentleman of great eminence in the literary world; but if the testimony of one who was on board the ship, and who made an extract from the journal in its rude

uncorrected state, may be relied on, there seems no reason to ascribe the merit of the work to any other person than him whose name it goes under.

The want of success which attended captain Cook's attempt to discover a southern continent, did not discourage another plan being resolved on, which had been recommended some time before. This was no other than the finding out a north-west passage, which some had conceived to be a practicable scheme. The dangers which our navigator had twice braved, would have exempted him from being solicited a third time to venture his person in unknown countries, amongst desert islands, inhospitable climates, and in the midst of savages; but, on his opinion being asked concerning the person who would be most proper to execute this design, he once more relinquished the quiet and comforts of domestic life, to engage in scenes of turbulence and confusion, of difficulty and danger. His intrepid spirit and inquisitive mind induced him again to offer his services; and they were accepted without hesitation. The manner in which he had deported himself on former occasions, left no room to suppose that a fitter man could be selected. He prepared for his departure with the utmost alacrity, and actually sailed in the month of July 1776.

A few months after his departure from England, notwithstanding he was then absent, the Royal Society voted him Sir Godfrey Copley's gold-medal, as a reward for the account which he had transmitted to that body, of the method taken to preserve the health of the crew of his ship; and Sir John Pringle, in his oration of 30th November, pronounced an high eulogium upon him.

This honourable testimony to the merit of our gallant commander, never came to his knowledge.—While his friends were waiting with the most earnest solicitude for tidings concerning him, and the whole nation expressed an anxious impatience to be informed of his success, advice was received from captain Clerke, in a letter dated at Kamtschatka, the 8th day of June 1779; from which, and from other accounts, we learn, "That captain Cook, after he had passed the Cape of Good Hope, had continued his course along Van Diemen's Land and New Zealand. He arrived happily in August 1777 at the island of Otaheite, where he landed Omiah, a native of the island, in perfect health: That since the last voyage of captain Cook to that island, the Spaniards had been there twice, and staid some months, and their ships had left all sorts of birds and domestic animals, but only of the male species; so that they received the cows and the she-goats that captain Cook brought with great pleasure. He left that island in the month of December following; and after having made several new discoveries in the South Sea, he arrived in the month of March 1778 on the coasts of America, situated in the south of Kamtschatka. A leak being discovered in captain Cook's ship the Resolution, and finding a very stormy sea, he was obliged to anchor in a bay in that part of the coast. After having repaired his own ship, they both put to sea; and sailing along the coast, they at last luckily discovered the strait between Asia and America. The two parts of the world presented only, at that height of latitude, a low barren land without any shelter, and a sea of a

very

very middling depth. They continued their route till they perceived distinctly the American coast extending to the north-east. He then thought himself arrived near to the bounds of his wives; but when he came to 70° 45' Lat. and 198° of Long. (probably reckoning from Greenwich), he met with impenetrable mountains of ice, which obliged him to turn towards the south. He cast anchor near the island Unalafcha, whence his letter is dated. He fixes that island in 53, 55 Lat. and 192, 30 Long. consequently giving that island a more western and southern position than is in the new general chart of Russia.

"As he then found himself to the east of Sandwich Island, which he had passed in his voyage, he reasonably thought he must meet with other islands; he therefore sailed again, in order to pass the autumn and the winter in a more temperate climate. He actually discovered divers other islands, which appeared to him extremely fertile, and where the inhabitants had raised stone-walls upon the heights for their defence. He cast anchor at one of these islands, named *O-nay-be*, in the gulph of Caracah-Coffa, and treated very amicably with the natives, who paid him almost divine honours. After he had refreshed his people, one of whom only had died in the voyage, and two others had fallen sick, he was already got under sail, when a furious storm hurt his mizen-mast, which obliged him to return to the gulph to repair it. The islanders became every day more bold, and most clearly demonstrated their inclination for theft; which went so far as to steal one of his boats. Captain Cook, willing to seek justice for this robbery, went on shore with his lieutenant, and ten or twelve of his crew. He advanced towards a large body of the inhabitants, who always paid him great respect, and accosted their chief. Whilst the negotiation was carrying on, the insolence of one of the islanders, who was in the throng, obliged him to fire on him with his musket, loaded only with small-shot, which did not even penetrate the mat with which he was covered. The Indians began then to be enraged; and when the lieutenant had at length fired and killed his man, the whole troop fell on the body: and as soon as the sailors had discharged their pieces, they did not give them time to load again, but killed captain Cook and four of his people, forcing the others, partly wounded, to make their escape under the favour of the fire of their pinnace.

"This fatal event happened on the 14th February 1779. A council was then called of the officers, to determine whether their commander's death should not be revenged in an exemplary manner; but it was thought most advisable to keep on the defensive until the mast was repaired. In the mean time captain Clerke made friends with the savages, and quitted the island to return to Kamtschatka, where he wintered in Port Awatscha, from the 1st of January that year till the month of June, and then failed to discover (as he writes word) more exactly the islands between Kamtschatka and America."

Captain Cook was a married man, and left several children behind him. On each of these his majesty has settled a pension of 25 l. a-year, and 200 l. a-year on his widow. It is remarkable, if true as reported, that captain Cook was godfather to his wife; and at the very time she was christened, declared that he had

determined on the union which afterwards took place between them.

Few men have been more regretted than captain Cook. He possessed all the qualities which could insure the esteem of mankind. To the most undaunted courage he added a most persevering resolution. He acquired the love of his seamen, as well by the soft as by stern virtues; being equally gentle and humane as he was commanding and intrepid. Without being possessed of much literature, or cultivating letters, he acquitted himself with credit even where the talents of writing were required. No man seemed so well formed for enterprises such as he was engaged in. He was fond of the pursuit, and sacrificed every consideration to them. He owed his rise entirely to his merit; and retained the modesty of his early state after he had risen beyond the expectations of his friends, and equal to his own.

COPYHOLD, (*Encycl.*) See TENURE and VILLENAGE, (*Encycl.*)

CORAL, (*Encycl.*) The nature and origin of coral has long been a subject of much dispute. Some have supposed that it is a stone; others a plant; and it has been almost universally believed that it was soft while in the sea, but grew hard on being taken out of it. But Boccone examined coral in the water, before it was taken up into the air, and invariably found it hard, except at its extremities, whence, by pressing it, flowed a small quantity of milky fluid, already taken notice of. We may therefore infer, that there is more of imagination than of truth in the name *gorgonium*, which the ancients gave to coral, and designed to show that Medusa's head did not convert objects into stone, more surely than coral became petrified as soon as it appeared in the air.

M. de Peyssonnel of Marseilles, has, in consequence of a series of experiments and observations from about the year 1720 to 1750, introduced a new system with respect to the nature and production of coral, and similar marine substances. Those bodies, which the count de Marigli imagined to be flowers, this ingenious naturalist discovered to be insects inhabiting the coral; for upon taking branches of it out of the water, the flowers, which proceeded from a number of white points answering to the holes that pierced the bark, and the radiation of which resembled the flower of the olive-tree, entered into the bark and disappeared; but upon being again restored to the water, they were some hours after perceptible. These flowers spread on white paper lost their transparency, and became red as they dried. The holes in the bark correspond to small cavities upon the substance of the coral; and when the bark is removed, there may be seen an infinite quantity of little tubes connecting the bark with the inner substance, besides a great number of small glands adhering to them; and from these tubes and glands the milky juice of coral issues forth: the holes in the bark are the openings through which the insects that form these substances for their habitation come forth; and those cavities which are partly in the bark and partly in the substance, are the cells which they inhabit. The organs of the animal are contained in the tubes, and the glandules are the extremities of his feet, and the milky liquor is the blood and juice of

Copper-plate
||
Coral.

Coral.

of the animal, which are more or less abundant in proportion to its health and vigour. When the insects are dead, they corrupt, and communicate to the water the smell of putrid fish. This juice or liquor runs along the furrows perceived upon the proper substance or body of coral, and stopping by little and little becomes fixed and hard, and is changed into stone; and being stopped in the bark, causes the coral to increase proportionally and in every direction. In forming coral, and other marine productions of this class, the animal labours like those of the stercoraceous kind, each according to his species; and their productions vary according to their several forms, magnitudes, and colours.

The coral insect, or polype, M. Peyssonnel observes, expands itself in water, and contracts itself in air, or when it is touched with the hand in water, or acid liquors are poured upon it: and he actually saw these insects move their claws or legs, and expand themselves; when the sea-water containing coral was placed near the fire, and keep them in their expanded state when separated from the coral in boiling water. Broken branches of coral have been observed to fasten themselves to other branches, and have continued to grow; and this is the case, when they are connected with detached pieces of rock and other substances, from which no nourishment could be derived. The coral insects in their cells, not having been injured, continue their operations; and as they draw no nourishment from the stone of the coral, they are able to increase in a detached and separate state. Coral was found to be equally red in the sea as out of it; and it was more shining when just taken out of the water, than even when it is polished; and the bark by being dried becomes somewhat pale. M. Peyssonnel found that it grows in different directions, sometimes perpendicularly downwards, sometimes horizontally, and sometimes upwards; and in the caverns of the sea, open to every exposure.

This system was little regarded, though first communicated to the Academy of Sciences at Paris in 1727, till Mr Trembley's discovery of the fresh-water polype; but since that time, it has been confirmed by the observations of M. Bernard de Jussieu on the sea-coasts of Normandy, and those of M. de Reaumur near Rochelle. M. Donati of Turin has also adopted the same hypothesis, viz. that coral is a mass of animals of the polype kind; and instead of representing the polype beds and cells which they contain as the work of polypes, he thinks it more just to say, that coral and other coralline bodies have the same relation to the polypes united to them, that there is between the shell of a snail and the snail itself, or the bones of an animal and the animal itself.

The same system has also been excellently illustrated and established by Mr Ellis, in answer to the objections of Dr Baister of Zealand, and Dr Pallas of Berlin, who still refer corallines to the vegetable kingdom.

There are properly but three kinds of coral; red, white, and black: the black is the rarest, and most esteemed; but the red was formerly used in medicine. It must be chosen thick, smooth, and shining, and of a beautiful red, not covered with any tartareous matter. However, this substance is now scarce ever prescribed by any intelligent practitioner.

CORALLINES, in natural history, were formerly reckoned a genus of plants, and Mr Tournefort enumerates 36 species of them; but in the Linnæan system they belong to the class of zoophytes, and are defined by modern naturalists to be submarine plant-like bodies, that consist of many slender finely divided and jointed branches, resembling some species of moss; or animals growing in the form of plants, having their stems fixed to other bodies: these stems are composed of capillary tubes, whose extremities pass through a calcareous crust, and open into pores on the surface. The branches are often jointed, and always subdivided into smaller branches, which are either loose and unconnected, or joined as if they were glued together. They are distinguished from plants by their texture and hardness: they also yield in distillation a considerable quantity of volatile salt; and their smell, in burning, resembles that of burnt horns and other animal substances. Many of the corallines seem to consist of a single tube, containing a single parent animal. Every branch emitted contains an offspring of this parent dependent upon it, and yet capable of producing its like in the emission of a new branch. Others consist of many such tubes united, rising up together, and encircling the deserted tubes of their progenitors, whose exuvie become the substratum of a rising generation. Mr Ellis distributes corallines into the *vesiculated*, *tubular*, *celliferous*, and *articulated* kinds.

Vesiculated corallines are distinguished by their horny hollow ramifications: most of them are furnished with little denticles on their branches, like leaves on mosses; and at certain seasons of the year they are furnished with small bodies like bladders, proceeding from their stems and branches, and differing in form according to the different species. Their colour, when dry, is of a yellowish or pale brown, and their nature is elastic. They are found adhering to rocks, shells, and fucuses, by small root-like tubes: they recover their form in water, after having been dried; and when put into vinegar, they cause no effervescence. See Plate CCCXV. fig. 1. *a* which represents the sea-tamarisk in its natural size, and *A* in which the denticles are magnified. Fig. 2. *b*, *B*, is the sea-cypress; fig. 3. *c*, *d*, *CD*, the small climbing coralline with well shaped cups.

Tubular corallines are composed of a number of simple tubes, growing up nearly together; or of such branched ones as have neither denticles nor vesicles. These are horny and elastic like the former, and recover their original form in water. Some of them appear wrinkled like the wind-pipe, and others like the intestines of small animals. See fig. 4. *E*.

Celliferous corallines are those which appear, when magnified, to be fine thin cells, the habitations of small animals connected together, and disposed in a variety of elegant forms like branches. These effervesce with acids. See fig. 5. *f* and *F*.

Articulated corallines consist of short pieces of a stony or stercoraceous brittle matter, whose surface is covered with pores or cells, which are joined by a tough, membranous, flexible substance, composed of many small tubes of the like nature compacted together. The stony part is soluble in vinegar, and the other part remains entire. See Plate CCCXVI. fig. 1.

See the description and drawings of a great variety of

Corallines

of species belonging to each class, in Ellis's Nat. Hist. above cited. *a*, *A*, (fig. 6.) is the coralline of the shops. It is fixed to rocks and shells by stony joints, which, as they rise, are united to others by extremely fine and slender tubes: These may be discovered by a good eye, or a common magnifier. As the stems extend themselves, they become pennated by side-branches, which come out opposite to each other, and are jointed in the same manner; the joints of this species are like the upper part of an inverted cone, but a little compressed: The whole surface is covered over with very minute circular-shaped cells like pores; see *B*, and *B* 1, where they are higher magnified. *B* 2, shows the cross section highly magnified. If a branch of this coralline is put into vinegar, these cells are dissolved with the whole cretaceous surface; instead of which there appear rows of minute ramifications, which seem to have communicated with each of these cells. Upon some specimens of this coralline, we may observe little small figures like seed-vessels, with which the branches frequently terminate: They are also found on the sides, as may be seen at *A*, where they are magnified.—When a branch is rendered soft by being steeped in vinegar, there may be squeezed out from the little knobs at the ends and sides, small twisted figures, like those at *A* 1, which are magnified higher at *A* 2.—We frequently find this coralline of different colours, as red, green, ash, and white; but all of it, by being exposed to the sun and air on the shore, becomes white.

The ancients have said great things of the virtues of the common coralline. Dioscorides prescribes it for mitigating the pain of the gout, and for preventing stagnations of the humours in any part; he says nothing of its virtues against worms, which are what we alone esteem it for. We give it in powder from 10 grains to a scruple or half a dram twice a day in these cases, and that with a considerable good effect.

Besides the above, Mr Ellis enumerates other genera of marine productions; as the keratophyta, eschara, sponges, and alcyonium; all which are the nests or matrices of sea-animals. See POLYPE. The last class of marine bodies is formed like funguses of various figures, and with different sorts of covering: some having a gritty, and some a callous skin, with a spongy substance in the inside: other species are of a fleshy substance.

CORRALLOIDES (FRUITICES.) See ESCHARA and KERATOPHYTA, in this APPENDIX.

CORNS, in surgery, hard excrescences, consisting of indurations of the skin arising on the toes, and sometimes on the sides of the feet, where they are much exposed to the pressure of the shoes. By degrees they press themselves farther down between the muscular fibres on these parts, and by their irritation occasion extreme pain. Many cures have been prescribed, but the total removal of them is always found to be attended with great difficulty. It has been recommended to soften them with plasters and then to pull them up by the roots, to apply caustic, &c. A piece of raw beef laid on by way of plaster, and frequently shifted, is also said to be effectual; but the best cure is to bathe them frequently in warm water, and pare away as much as possible of the indurated skin without drawing blood.

CORRODY, in law. See REVENUE, (Encycl.)
CORYLUS, (Encycl.) See also HAZEL, (Encycl.)
CORYPHA, MOUNTAIN-Palm, or Cabbage-Tree, in botany; a genus of the order of palmæ, belonging to the monœcia class of plants. There is only one species, the umbracula, a native of the West Indies, where it is said to rise to the height of 150 and 200 feet. It is by some authors called the *palmetto royal*; and well, says Hughes in his Natural History of Barbadoes, may it be called *royal*, since neither the tall cedars of Lebanon, nor any of the trees of the forest, are equal to it in height, beauty, or proportion. It is generally as straight as an arrow: near the earth it is about seven feet in circumference, but tapers as it ascends. The bark is of an ash-colour, till within 25 or 30 feet of the extremity of the tree; when it alters at once to a deep sea-green, which continues to the top. Upon removing the large leaves, or branches, which surround the top of the trunk a little way above the beginning of the green bark just mentioned, what is called the *cabbage* is discovered lying in many thin, snow-white, brittle flakes, in taste resembling an almond, but sweeter. This substance, which cannot be procured without destroying the tree, is boiled, and eaten with mutton by the inhabitants of the West Indies, in the same manner as turnips and cabbage are with us; it is likewise pickled, and sent to Europe, where it is esteemed an exquisite delicacy.

In the pith of the trunk of the cabbage-palms, when felled, there breeds a kind of worms, or grubs, which are eaten and esteemed a great delicacy by the French of Martinico, St Domingo, and the adjoining islands. These worms, says father Labat, are about two inches long, and of the thickness of one's finger; the head is black, and attached to the body without any distinction of neck. Their preparation for the table is as follows: They are strung on wooden skewers before a fire, and as soon as heated, are rubbed over with raspings of crust, salt, pepper, and nutmeg; this powder absorbs all the fat, which during the cookery would otherwise escape; when properly roasted they are served up with orange or citron sauce. These worms being exposed for some time to the sun, are said to yield an oil which is of great efficacy in the piles. The oil in question, says Labat, is never to be heated before its application to the part affected; as repeated experiments have evinced that its spirit is totally dissipated by the fire.

rides; for which intention they are dried and powdered, and given in doses from 12 grains to a scruple. The house cricket only flies from the light, as many other insects do; it feeds almost on every thing. The males only chirp; and their monotony, however disagreeable to some people, is pleasant enough to their own females, for it is the voice of love; and it is continual, night and day, except in very cold weather. They become habituated to bear all kinds of noise; but the field cricket is very timorous, and chirps only in the heat of the finest days of summer.

CULEX, the GNAT; a genus of insects belonging to the order of diptera. The mouth is formed by a flexible sheath, inclosing bristles pointed like stings. The antennæ of the males are filiform; those of the females feathered. There are seven species. These insects, too well known by the severe punctures they inflict, and the itchings thence arising, afford a most interesting history. Before they turn to flying insects, they have been in some manner fishes, under two different forms. You may observe in stagnating waters, from the beginning of May till winter, small grubs with their heads downwards, their hinder-parts on the surface of the water; from which part arises sideways a kind of vent-hole, or small hollow tube like a funnel, and this is the organ of respiration. The head is armed with hooks, that serve to seize on insects and bits of grass on which it feeds. On the sides are placed four small fins, by the help of which the insect swims about, and dives to the bottom. These larvæ retain their form during a fortnight or three weeks, after which period they turn to chrysalids. All the parts of the winged insect are distinguishable through the outward robe that shrouds them. The chrysalids are rolled up into spirals. The situation and shape of the windpipe is then altered; it consists of two tubes near the head, which occupy the place of the stigmata, through which the winged insect is one day to breathe. These chrysalids, constantly on the surface of the water in order to draw breath, abstain now from eating; but upon the least motion are seen to unroll themselves, and plunge to the bottom, by means of little paddles situated at their hinder-part. After three or four days strict fasting, they pass to the state of gnats. A moment before, water was its element; but now, become an aerial insect, he can no longer exist in it. He swells his head, and bursts his inclosure. The robe he lately wore turns to a ship, of which the insect is the mast and sail. If at the instant the gnat displays his wings there arises a breeze, it proves to him a dreadful hurricane; the water gets into the ship, and the insect, who is not yet loosened from it, sinks and is lost. But in calm weather, the gnat forsakes his slough, dries himself, flies into the air, seeks to pump the alimentary juice of leaves, or the blood of man and beasts. The sting which our naked eye discovers, is but a tube, containing five or six spicula of exquisite minuteness; some dentated at their extremity like the head of an arrow, others sharp-edged like razors. These spicula introduced into the veins, act as pump-suckers, into which the blood ascends by reason of the smallness of the capillary tubes. The insect injects a small quantity of liquor into the wound, by which the blood be-

comes more fluid, and is seen through the microscope passing through those spicula. The animal swells, grows red, and does not quit its hold till it has gorged itself. The liquor it has injected, causes by its fermenting, that disagreeable itching which we experience; and which may be removed by volatile alkali, or by scratching the part newly stung, and washing it with cold water; for later, the venom ferments, and you would only increase the tumour and the itching. Rubbing one's self at night with fuller's-earth and water, lessens the pain and inflammation. Gnats perform their copulation in the air. The female deposits her eggs on the water; by the help of her moveable hinder part and her legs, placing them one by the side of another in the form of a little boat. This vessel, composed of two or three hundred eggs, swims on the water for two or three days, after which they are hatched. If storm arises, the boats are sunk. Every month there is a fresh progeny of these insects. Were they not devoured by swallows, other birds, and by several carnivorous insects, the air would be darkened by them.

Gnats in this country, however troublesome they may be, do not make us feel them so severely as the musketo-flies (*culex pipiens*) do in foreign parts. In the day-time or at night they come into the houses; and when the people are gone to bed they begin their disagreeable humming, approach always nearer to the bed, and at last suck up so much blood that they can hardly fly away. Their bite causes blisters in people of a delicate complexion. When the weather has been cool for some days, the musketoes disappear; but when it changes again, and especially after a rain, they gather frequently in such quantities about the houses, that their numbers are astonishing. In sultry evenings they accompany the cattle in great swarms, from the woods to the houses or to town; and when they are drove before the houses, the gnats fly in wherever they can. In the greatest heat of summer, they are so numerous in some places, that the air seems to be quite full of them, especially near swamps and stagnant waters, such as the river Morris in New Jersey. The inhabitants therefore make a fire before their houses to expel these disagreeable guests by the smoke.

CULLODEN, a place in Scotland within two miles of Inverness, chiefly remarkable for a complete victory gained over the rebels on the 16th of April 1746. That day the royal army, commanded by the late duke of Cumberland, began their march from Nairn, formed into five lines of three battalions each; headed by major-general Huske on the left, lord Semple on the right, and brigadier Mordaunt in the centre; flanked by the horse under the generals Hawley and Bland, who at the same time covered the cannon on the right and left. In this order they marched about eight miles, when a detachment of Kinglton's horse, and of the Highlanders, having advanced before the rest of the army, discovered the van of the rebels commanded by the young pretender. Both armies immediately formed in the order and numbers, shown in the annexed scheme.

About two in the afternoon the rebels began to cannonade the king's army: but their artillery being ill served, did little execution; while the fire from their enemies was severely felt, and occasioned great disorder.

Culloden

disorder. The rebels then made a push at the right of the royal army, in order to draw the troops forward; but finding themselves disappointed, they turned their whole force on the left; falling chiefly on Barrrell's and Monroe's regiments, where they attempted to flank the king's front-line. But this design also was defeated by the advancing of Wolfe's regiment, while in the mean time the cannon kept playing upon them with cartridge-shot. General Hawley, with some Highlanders, had opened a passage through some stone-walls to the right for the horse which advanced on that side; while the horse on the king's right wheeled off upon their left, dispersed their body of reserve, and met in the centre of their front-line in their rear; when being repulsed in the front, and great numbers of them cut off, the rebels fell into very great confusion.

A dreadful carnage was made by the cavalry on their backs; however, some part of the foot still preserved their order: but the Kingston's horse, from the reserve, galloped up briskly, and falling on the fugitives, did terrible execution. A total defeat instantly took place, with the loss of 2500 killed, wounded, and prisoners, on the part of the rebels; while the royalists lost not above 200. The young pretender had his horse shot under him during the engagement; and after the battle retired to the house of a factor of lord Lovat, about ten miles from Inverness, where he staid that night. Next day he set out for Fort-Augustus, from whence he pursued his journey through wild deserts with great difficulty and distress, till at last he safely reached France, as related under the article BATTLE OF CULLODEN. The D. of Perth's reg. and Ld. Ogilvie's, not to fire without positive order; and to keep close, as a fresh corps de reserve 800.—In all 8350.

CURCULIO, (Enceyl.) These insects are divided into the following families. 1. Those which have the rostrum longer than the thorax, and whose thighs are simple. 2. Those which have the rostrum longer than the thorax, and the thighs thicker and made for leaping. 3. Those which have the rostrum longer than the thorax, and the thighs dentated. 4. Those which have dentated thighs, and a rostrum shorter than the thorax. 5. Those whose thighs are without teeth or spines, and the rostrum shorter than the thorax.

The larvæ of the curculiones differ not from those of

most coleopterous insects. They bear a resemblance to oblong foot worms. They are provided anteriorly with six scaly legs, and their head is likewise scaly. But the places where those larvæ dwell, and their transformations, afford some singularities. Some species of them, that are dreaded for the mischief they do in granaries, find means to introduce themselves, while yet small, into grains of corn, and there make their abode. It is very difficult to discover them, as they lie concealed within the grain. There they grow at leisure, enlarging their dwelling-place as they grow, at the

Curculio

||

Dæmon.

Barren on
Insects.

expende of the interior meal of the grain on which they feed. Corn-lofts are often laid waste by these insects, whose numbers are sometimes so great as to devour and destroy all the corn. When the insect, after having eat up the meal, is come to its full size, it remains within the grain, hidden under the empty husk, which subsists alone; and there transformed, it becomes a chrysalis, nor does it leave it till a perfect insect, making its way through the husk of the grain. It is no easy matter to discover by the eye the grains of corn thus attacked and hollowed out by these insects, as they outwardly appear large and full: but the condition the curculio has reduced them to, renders them much lighter; and if you throw corn infested by these insects into water, all the tainted grains will swim, and the rest sink to the bottom. Other larvæ of curculiones are not so fond of corn, but fix in the same manner on several other seeds. Beans, pease, and lentils, that are preserved dry, are liable to be spoiled by these little animals, which prey upon the inward part of the grain, where they have taken up their habitation, and do not come forth till they have completed their transformation, by breaking through the outward husk of the grain: this is discoverable by casting those grains into water; those that swim are generally perforated by the curculiones. Other species are lodged in the inside of plants. The heads of artichokes and thistles are often bored through and eaten away by the larvæ of large curculiones. Another species smaller, but singular, pierces and inwardly consumes the leaves of elms. It frequently happens that almost all the leaves of an elm appear yellow, and as it were dead towards one of their edges, while the whole remainder of the leaf is green. Upon inspecting those leaves, the dead part appears to form a kind of bag or small bladder. The two lamina or outward pellicles of the leaf, as well above as below, are en-

tire, but distant and separated from each other, whilst the parenchyma that lies between them has been consumed by several small larvæ of the curculio, that have made themselves that dwelling, in which they may be met with. After their transformation they come forth, by piercing the kind of bladder, and give being to a curculio that is brown, small, and hard to catch, by reason of the nimbleness with which it leaps. The property of leaping, allotted to this single species, depends on the shape and length of its hinder legs.

CUSTOM and HABIT. Delete the References to *Emotions and Passions*.

CYMBAL, (Encycl.) Cassiodorus and Isidore call this instrument *acetabulum*, the name of a cup or cavity of a bone wherein another is articulated; and Xenophon compares it to a horse's hoof; whence it must have been hollow: which appears, too, from the figure of several other things denominated from it; as a basin, caldron, goblet, cask; and even a shoe, such as those of Empedocles, which were of brass.

In reality, the ancient cymbals appear to have been very different from our kettle-drums, and their use of another kind: to their exterior cavity was fastened a handle; whence Pliny compares them to the upper part of the thigh, and Rabanus to phials.

They were struck against one another, in cadence, and made a very acute sound. Their invention was attributed to Cybele; whence their use in feasts and sacrifices: setting aside this occasion, they were seldom used but by dissolute and effeminate people. M. Lampe, who has written expressly on the subject, attributes the invention to the Curetes, or inhabitants of mount Ida in Crete: it is certain these, as well as the Corybantes, or guards of the kings of Crete, and those of Rhodes and Samothracia, were reputed to excel in the music of the cymbal.

D.

DÆMON, (Encycl.) This word is by some derived from the Greek *δαίμων*, "knowing, or intelligent;" by some from *δαιρέω*, "to distribute." Either of these derivations agrees with the office ascribed to dæmons by the ancient heathens, as the spirits intrusted with the inspection and government of mankind. According to the philosophers, dæmons held a middle rank between the celestial gods and men on earth, and carried on all intercourse between them; conveying the addresses of men to the gods, and divine benefits to men. Many were of opinion that the celestial divinities did not concern themselves with human affairs, but left the management of them entirely to these subaltern deities. Hence they became the objects of worship, though those who were more immediately so were the spirits of men who were thought to have become dæmons or deities after departing from their bodies. Hesiod and other poets who have written concerning the ancient history or traditions on which the public faith was founded, assert, that the men of the golden age, who were very good, became dæmons after death, and dispensers of good things to mankind. In this sense, according to some, the word *dæmon* (though constantly translated *devil*) is also frequently taken in Scripture, both in the Old and New

Testament. Besides the two foregoing kinds of dæmons, the fathers as well as philosophers asserted the existence of another, viz. such as spring from the congress of superior beings with women; and in the theology of the fathers, these were the worst of all.

DAMPS, (Encycl.) Among the other uses to which dephlogiticated air might be applied, Mr Cavallo reckons that of securing people from the dangerous effects of damps in mines, and other subterraneous places. "If a large bladder," says he, "into which a solution of lime in water is introduced, be filled with dephlogiticated air, and a small wooden or glass pipe be adapted to its neck, a man may hold that pipe in his mouth, and may breathe the dephlogiticated air; and thus equipped he may enter into these subterranean places, amidst the various elastic fluids contained in them. A large bladder of dephlogiticated air will serve for above a quarter of an hour, which is a length of time sufficient for various purposes; besides, if longer time is required to be spent in these places, a person may have two or more bladders of dephlogiticated air along with him, and may shift as soon as the air of one is contaminated. Without the necessity of any more complicated apparatus, the bladders full of dephlogiticated air may be kept stopped by putting

corks

Custos

||

Damp.

bet, corks into the glafs or wooden pipes that are tied to their necks. This air might alfo be ufed for diving-bells."

DEBT, National. See NATIONAL and FUNDS. (*Encycl.*)

DEFORMITY, (*Encycl.*) Deformity is either natural or moral. Thefe are both referred by Mr Hutchifon to an internal fenfe; and our perceptions of them, as he fupposes, arife from an original arbitrary ftructure of our own minds, by which certain objects, when obferved, are rendered the occafions of certain fenfations and affections.

That many objects give no pleafure to our fenfe, is obvious. Many are certainly void of beauty; but then, fays this author, there is no form which feems neceffarily difagreeable of itfelf, when we dread no other evil from it, and compare it with nothing better of the kind. Many objects are naturally difpleafing and diftafteful to our external fenfes, as well as others pleafing and agreeable; as fmells, taftes, and fome feperate founds: but with regard to our fenfe of beauty, no compofition of objects which give not unpleafant fimple ideas, feems pofitively unpleafant or painful of itfelf, had we never obferved any thing better of the fame kind.

Had there been a fpecies of the form which we now denominate *ugly* or *deformed*, and had we never feen or expected greater beauty, we fhould have received no difguft from it; though the pleafure would not have been fo great in this form as in thofe we now admire. Our fenfe of beauty feems defigned to give us pofitive pleafure; but not pofitive pain or difguft, any farther than what arifes from difappointment.

There are indeed many faces which, at firft view, are apt to raife diflike. But this is generally not from any pofitive deformity; but either from want of expected beauty, or from the carrying fome natural indications of morally bad difpofitions, which we all acquire a faculty of difcerning in countenances, airs, and geftures. That this is not occafioned by any form pofitively difgufting, appears hence, that if, upon long acquaintance, we are fure of finding fweetnefs of temper, humanity, and cheerfulnefs, though the bodily form continues, it fhall give us no difguft. There are horrors raifed by fome objects, which are only the effect of fear for ourfelves, or compaffion towards others, when either reafon, or fome foolifh afociation of ideas, makes us apprehend danger; and not the effect of any thing in the form itfelf. For we find, that moft of thofe objects which excite horror at firft, when experience or reafon has removed the fear, may become the occafion of pleafure.

The cafual conjunction of ideas gives us difguft, where there is nothing difagreeable in the form itfelf. And this, in effect, is the caufe of moft of our fantaftic averfions to the figures of divers animals, &c. Thus ferpents of all kinds, and many infefts, really beautiful enough, are beheld with averfion by many people, who have got fome accidental ideas of mifchief afociated to them. A fimilar reafoning is applied to our perception of moral beauty and deformity. *Inquiry into the original of our Ideas of Beauty and Virtue*, paffim.

But it is more juft to diftinguifh between the fenfiments of delight or difguft, excited in us by beautiful

or deformed objects, which are effects of fome caufes, and the natural and real qualities of the perceived objects by which they are produced. There are objects,

fays an excellent writer, which have a natural aptitude to pleafe or offend, or between which and the contemplating mind there is a neceffary congruity or incongruity; and though the actual perception of the underftanding, and confequent feeling of the heart, in contemplating the actions and affections of moral agents, may exift in very different degrees, on account of the incidental obftructions arifing from bodily indifpofition, mental prejudices and biaffes, and the afociation of ideas; yet, to every rational mind properly difpofed, morally good actions muft for ever be acceptable, and can never of themfelves offend; and morally evil actions muft for ever be difagreeable, and can never of themfelves pleafe. What is right in actions and characters is beautiful and amiable, and gives pleafure; what is wrong is deformed and odious, and excites difguft: right and pleafure, wrong and pain, are as diftinct as caufe and effect. It is no lefs abfurd to maintain, that the perception of virtue is nothing diftinct from the reception of the pleafure refulting from it, than to infer, with fome metaphyficians, that folidity, extension, and figure, are only particular modes of infatiation, becaufe attended, whenever they are perceived, with fome fenfations of fight or touch. Thus does this author fhew, that moral beauty and deformity are real qualities of certain actions; in which confifts their aptitude to pleafe or difguft. With refpect to natural beauty, he obferves, that uniformity amidft variety pleafes, becaufe of the natures of variety and uniformity, which are fuch, that, whenever united, they are adapted to pleafe every free unbiaffed mind that difcerns them. He accounts for the pleafure they afford, without referring them to an arbitrary internal fenfe, by the following circumftances that attend them. They are more eafily comprehended by the mind: order and fymmetry give things their ftability and ftrength, and fubfervency to any valuable purpofe; regularity and order evidence art and defign. Diforder and confufion, whence deformity arifes, denote only the negation of regularity and order; or any arrangement and difpofition of things, which are not according to a law, rule, or plan, and prove not defign. Thefe are not pofitively difpleafing; except where we previously expected order, or where impotence or want of fkill appear, and the contriver has either failed of his defign or executed it ill. DODD (Dr William), an unfortunate diffenting Englifh divine, eldeft fon of the Rev. William Dodd, many years vicar of Bourne in Lincolnfhire, was born May 29. 1729. He was fent, at the age of 16, to the univerfity of Cambridge; and admitted, in the year 1745, a fizar of Clare-Hall. In 1749-50 he took the degree of B. A. with great honour, being upon that

occasion

Dodd
Dower.

occasion in the list of wranglers. Leaving the university, he imprudently married a Miss Mary Perkins in 1751, was ordained a deacon the same year, priest in 1753, and soon became a celebrated and popular preacher. His first preferment was the lectureship of West-Ham. In 1754 he was also chosen lecturer of St Olave's, Hart-Street; and in 1757 took the degree of M. A. at Cambridge. On the foundation of the Magdalen Hospital in 1758, he was a strenuous supporter of that charity, and soon after became preacher at the chapel of it. By the patronage of Bishop Squire, he in 1763 obtained a prebend of Brecon, and by the interest of some city-friends procured himself to be appointed one of the king's chaplains; soon after which, he had the education of the present earl of Chesham committed to his care. In 1766, he went to Cambridge, and took the degree of LL.D. At this period, the estimation in which he was held by the world was sufficient to give him expectations of preferment, and hopes of riches and honours; and these he might probably have acquired, had he possessed a common portion of prudence and discretion. But, impatient of his situation, and eager for advancement, he rashly fell upon means, which in the end were the occasion of his ruin. On the living of St George, Hanover-Square, becoming vacant, he wrote an anonymous letter to the chancellor's lady, offering 3000 guineas if by her assistance he was promoted to it. This being traced to him, complaint was immediately made to the king, and Dr Dodd was dismissed with disgrace from his office of chaplain. From this period he lived neglected, if not despised; and his extravagance still continuing, he became involved in difficulties, which tempted him to forge a bond from his late pupil lord Chesham, Feb. 4. 1777, for 4200l. which he actually received: but being detected, he was tried at the Old Bailey, found guilty, and received sentence of death; and, in spite of every application for mercy, was executed at Tyburn, June 27. 1777. Dr Dodd was a voluminous writer, and possessed considerable abilities, with little judgment and much vanity. An accurate list of his various writings is prefixed to his "Thoughts in Prison," ed. 1781.

DODONIAN, (*Encycl.*) The origin and occasion of this fable we have from Herodotus, who observes it was founded on this, that *palas*, which in the Thessalian language signifies a pigeon, does likewise signify a witch, or prophets. But what is more extraordinary is, another tradition among the poets, as if the very oaks of the forest of Dodona spoke, and delivered oracles. This fable is easily deduced from the former; the pigeons in the oaks being supposed to speak, it was no great slight of poetical fancy, to introduce the trees themselves speaking, &c.

The fountain of Dodona was in the temple of Jupiter. The ancient naturalists assure us, it had a property of rekindling torches, &c. when newly extinguished. This, no doubt, it did, by means of some sulphureous fumes exhaling from it; as we still find a fountain in Dauphiné, called the *burning fountain*, do. It is also said to have extinguished lighted torches; which is no great miracle, since plunging them into a place where the sulphur was too dense, or into the water, must have that effect.

DULSE, *Dulse*, or *Sweet Fucus*. See **FUCUS**, in this **APPENDIX**.

DUNSTAFFNAGE, a castle situated in the island of Skie, fabled to have been founded by Ewin a Pictish monarch, cotemporary with Julius Cæsar, naming it after himself, *Ewonium*. In fact, the founder is unknown; but it is certainly of great antiquity, and the first seat of the Pictish and Scottish princes. In this place was long preserved the famous stone the Palladium of North Britain; brought, says legend, out of Spain, where it was first used as a seat of justice by Gathelus, coeval with Moses. It continued here as the coronation-chair till the reign of Kenneth II. who removed it to Scone, in order to secure his reign; for according to the inscription,

*Ni fallat fortum, Sciti quocunque locatum
Invenient lapidem, regnare teneantur ibidem.*

The castle is square; the inside only 87 feet; partly ruinous, partly habitable. At three of the corners are round towers; one of them projects very little. The entrance is towards the sea at present by a staircase, in old times probably by a draw-bridge, which fell from a little gate-way. The masonry appears very ancient; the tops battlemented. This pile is seated on a rock, whose sides have been pared to render it precipitous, and to make it conform to the shape of the castle.

In 1307, this castle was possessed by Alexander Macdougall lord of Argyll, a friend to the English; but was that year reduced by Robert Bruce, when Macdougall sued for peace with that prince, and was received into favour.

We find, about the year 1455, this to have been a residence of the lords of the isles; for here James last earl of Douglas, after his defeat in Annandale, fled to Donald, the regulus of the time, and prevailed on him to take arms and carry on a plundering war against his monarch James II.

At a small distance from the castle is a ruined chapel, once an elegant building; and at one end an inclosure, a family-cemetery. Opposite to these is a high precipice, ending abrupt and turning suddenly toward the south-east. A person concealed in the recess of the rock, a little beyond the angle, surprises friends stationed at some distance beneath the precipice, with a very remarkable echo of any word, or even sentence, he pronounces; which reaches the last distinct and unbroken. The repetition is single, but remarkably clear.

| Water horchound, | <i>Lycopus europæus.</i> |

DYTISCUS. (*Encycl.*) The larvæ of the dytisci, water-beetle, or diver, are often met with in water. They are oblong, and have six fealy feet. Their body consists of eleven segments. The head is large, with

four filiform antennæ and a strong pair of jaws. The last segments of their body have rows of hairs on the sides; and the abdomen is terminated by two spines charged with the like hairs, forming a kind of plumes. These larvæ are frequently of a greenish variegated brown: they are lively, active, and extremely voracious: they devour and feed upon other water-insects, and often tear and destroy each other. The perfect insect is little inferior to its larvæ in voraciousness, but it can only exercise its cruelty on the larvæ; the perfect insects, like himself, being sheltered by the kind of scaly cuirass with which they are armed. This creature must be touched cautiously; for besides its power of giving a severe gripe with its jaws, it has moreover, under the thorax, another weapon, a long sharp spine, which it will drive into one's fingers by the effort it makes to move backwards. The eggs of the dytisci are rather large, and are by them inclosed in a kind of silky dusky cod, of a strong and thick texture, in form round, and terminated by a long appendix, or slender tail, of the same substance. These cods are often found in the water, and from them are brought forth the eggs and larvæ of the dytisci. The strength of these cods probably serves the insect to defend their eggs from the voraciousness of several other aquatic insects, and even from that of their fellow-dytisci, who would not spare them.

Many species of the perfect insect are common in stagnated waters, which they quit in the evening to fly about. They swim with incredible agility, making use of their hinder-legs after the fashion of oars. The elytra of the females are in general furrowed, and those of the male plain: when they first arrive at their perfect state, their elytra are almost transparent, and in many species of a beautiful dun colour, mingled with shades of greenish brown. The best method of catching them is with a hand-net or sieve; for they are so nimble, and exercise their defensive weapons so often, and with such painful success, to those who endeavour to catch them, that they are very often obliged to let them escape; the easiest way to kill them, is to let them fall into boiling hot water, which instantly destroys them.

E.

EAR-ACH, in medicine. This disorder affects the concha, and the whole meatus auditorius. It is attended with inflammation, tumours, punctation, erosion, tension, pulsation, and a sense of weight.

Extraneous bodies falling into the meatus auditorius, or whatever excites pain in other parts, may cause it here.

The quality of the wax may be faulty, and be a cause; but the most frequent causes are heat and cold: sometimes an acrid serum is secreted in the glands of the ear.

If the pain is violent, it seldom fails to bring on a fever, which is early attended with great restlessness; and a delirium, fainting, and often convulsions, are the consequence: for the membrane that lines the ear is exquisitely sensible, and fully strewed with nerves; besides, membranes which adhere to bones have a more than ordinary sensibility.

In the beginning, whilst the pain is not very con-

derable, a little warm olive-oil dropped into the ear will often relieve. If cold is the cause, keep the head warm. If there is inflammation and tumour, which will be known by the throbbing pain, a suppuration may be encouraged by cataplasms applied warm on the outer ear; but if the state of suppuration is not manifestly near, endeavour by bleeding, purging, and discutients applied to the ear, to remove the inflammation and pain. If external heat was the cause, bleed, and give daily a moderate dose of Glauber's salt as a purge, until the pain abates, or until there is reason to suspect a suppuration: an opiate may be given at night when the pain is violent. When acrid fluxions are the cause, inject a warm infusion of poppy-heads in water. When living insects have crept into the ear, blow the smoke of tobacco therein, and then pour in warm oil. If purulent matter discharges itself, inject tepid water, mixed with a little soap or honey of roses. Besides the above-mentioned, blisters behind the ears, Motherby's Med. Diss.

EDUCATION, (*Encycl.*) The follies of a too delicate education are well expressed in that device of an ape; which by over caressing and hugging its younges, strangles them; with this motto, *complexando necat*. Octavius Ferrarius has a very good Latin treatise on the subject of education, intitled *Chiron*, the name of the centaur who was Achilles's tutor.

Mr Locke's excellent treatise of education is known to every body. Quintilian employs the second chapter of his first book in inquiring whether a domestic or a college education be preferable, i. e. whether it be better to bring up one's children at home, or send them to the colleges and public schools. After urging all that can be said on either side, he concludes for a college or school education.

The plan of education, whether it be domestic or collegiate, should be suited to the station and views of parents, and to the genius of their children; and it is also right to consult their constitution and inclination. It is of great importance, that those who are destined to occupy superior stations in society, should enjoy the benefits of an enlarged and liberal education; that they should be furnished with every substantial and ornamental accomplishment; and those that are intended for any particular profession or employment, should be principally directed to those studies which are appropriated to their respective views; and in every rank of life, an attention to the morals of youth should be a primary object. Though the municipal laws of most countries have made no provision for constraining a parent to bestow a proper education on his children; yet in the case of religion, they are under peculiar restrictions in our own country. Some of these restrictions, as they affect protestants who dissent from the religion of the state, may be thought both impolitic and injurious, and have, therefore, lately been considerably relaxed; but those which are to prevent the progress of popery, are prudent and necessary. Thus, if any person sends a child under his care beyond the seas, to be instructed in any Popish college,

&c. in the principles of the Popish religion, or shall contribute towards his maintenance, he shall forfeit one hundred pounds, besides the disabilities incurred by the child so sent, (1 Jac. 1. cap. 4. and 3 Jac. 1. cap. 5. 11 and 12 W. III. cap. 4.); and both shall be incapable of suing in law or equity, of being executor or administrator, of enjoying any legacy or deed of gift, or of bearing any office in the realm; and he shall forfeit all his goods and chattels, and likewise all his real estate for life, 3 Car. 1. cap. 2.

EFFLORESCENCE, (*Encycl.*) Besides the common crystallization of salts, all of them have the property of appearing in the form of an efflorescence, or small saline spiculae, when mixed with any thick substance, particularly lime. Whatever salt happens to be made use of, there is little or no difference in the efflorescence. Thus, in butter very much salted, the sea-salt shoots in the form of long spiculae, though the sea-salt itself never shoots but in the form of cubical crystals. In like manner Glauber's salt will appear in the form of an efflorescence, as well as the fossil alkali, &c. nor will the form of the crystals of the efflorescence be perceptibly different from those of sea-salt. The efflorescences which we see very commonly upon walls are in general Glauber's salt. In some cases (but seldom in such efflorescences as we have examined), they are composed of fossil alkali. The reason of these differences is not known. In almost all cases of this kind there seems to be a real growth of salt. On one spot of a plaster wall about two feet square, which we observed particularly, this growth was very evident. The produce was a true Glauber's salt; and by frequently taking off the efflorescence, eight ounces were procured; nor did the prolific virtue of the wall seem to be in the least impaired by the waste.

E N T O M O L O G Y.

ENTOMOLOGY, the science of insects, or that part of zoology which treats of insects.

Whoever is desirous of attaining a systematic knowledge of insects, ought primarily to be solicitous about acquiring the terms made use of in the science, that so he may be able rightly to denominate every part of an insect. The student is first to know what an insect is, lest he mistake hippocampi, and other amphibious animals, for them, as was formerly done; or confound them with the *vermes*, which Linnaeus first distinguished from insects, and which differ as essentially from them as the class mammalia do from birds. Every insect is furnished with a head, antennæ, and feet, of all which the *vermes* are destitute. All insects have six or more feet; they respire through pores placed on the

sides of their bodies, and which are termed *spiracula*; their skin is externally hard, and serves them instead of bones, of which they have internally none. From this definition, the *acus marina* is evidently no insect. But the antennæ placed on the fore-part of the head, constitute the principal distinction. These are jointed and moveable in every part, in which they differ from the horns of other animals: they are organs conveying some kind of sense; but we have no more idea of what this kind of sense is, than a man has, who, without eyes, attempts to determine the particular action of the rays of light on the retina of the eye, or to explain the changes which from thence take place in the human mind. That they are the organs of some kind of sense, is apparent from their perpetually moving them

Efflorescence.
||
Entomology.

them forward; yet the hard crust with which they are invested, and their shortness in flies and other insects, would induce one to believe them not to be the organs of touch: Mr Barbut supposes them to constitute or to contain the organs of hearing. That they are tubular, and filled with air, and some kind of humour, appears from the antennæ of butterflies immersed in water.—To come now to the terms of the art. A knowledge of the external parts of the body is first to be established; which, after the method of anatomists, we divide into head, trunk, abdomen, and extremities.

SECT. I. *External parts of the Body.*

I. CAPUT, the HEAD. This part in insects without brain. The difference between the brain and spinal marrow consists in the former being a medullary part organized. We do not deny the existence of a medullary thread in the heads of insects, but we never could discover it to be organized: hence the hippocapna, or horse fly, will live, run, nay even copulate, after being deprived of its head; to say nothing of many others which are capable of living a long while in the same situation.

As they are not apparently furnished with ears, they have been apprehended incapable of hearing; as we can no more conceive that sense to exist without ears, than vision without eyes. That they are nevertheless susceptible of any shrill or loud noise, as well as fishes, is indisputable; but it has been supposed to be in a manner different from that of hearing. Mr Barbut, however, supposes them to possess this sense in a very distinct manner. Many insects, he observes, are well known to be endowed with the power of uttering sounds, such as large beetles, the bee, wasp, common fly, gnat, &c. The sphinx atropis squeaks, when hurt, nearly as loud as a mouse. Now, if insects are endowed with the power of uttering sounds, it certainly must be for some purpose. As they vary their cry occasionally, it must certainly be designed either to give notice of pleasure or pain, or some affection in the creature who possesses it. "The knowledge of their sounds (says our author) is undoubtedly confined to their tribe, and is a language intelligible to them only; saving when violence obliges the animal to exert the voice of nature in distress, craving compassion; then all animals understand the doleful cry. For instance, attack a bee or wasp near the hive or nest, or a few of them: the consequence of that assault will be, the animal or animals, by a different tone of voice, will express his or their disapprobation or pain; that sound is known to the hive to be plaintive, and that their brother or brethren require their assistance; and the offending party seldom escapes with impunity. Now, if they had not the sense of hearing, they could not have known the danger their brother or brethren were in by the alteration of their tone."

Another proof, which he reckons still more decisive, was taken from an observation made by himself a large spider in St James's park. This creature had made a very large web on a wooden railing; and was, at the time of observation, on one of the rails at a considerable distance from the place where a large fly entangled itself. Nevertheless, the moment the fly was entangled, the spider became sensible of it; though,

from the situation of the rail, he could not possibly have seen it. In this, however, Mr Barbut might possibly be deceived; because the spider was perhaps alarmed by the tremulous motion of the threads, occasioned by the fluttering of the fly; which he might well know how to distinguish from their vibration by the wind. The organ of hearing, in our author's opinion, is situated in the antennæ; both from their situation in the part of the head most favourable to such organs, their inward structure being moveable, the ears of most inferior animals being so. He has never considered the antennæ as either offensive or defensive, but has observed them to be endowed with an exquisite sense of feeling; that the animal appeared to be in agony when its antennæ were pinched; and that it takes care to avoid the touching any hard substance with them roughly. "This tenderness in the organ of hearing (says he) is common to all animals; and insects seem to be particularly tender in these parts by quickly withdrawing them from the touch."

Our author further observes, that the antennæ of all insects are composed of joints varying in size, form, and number. Those who are chiefly confined to live under water have their antennæ in general shorter than those who live on land. Some who roam at large in the air, have them long and slender. They are all hollow, and are rendered flexible by the joints, which are very visible in the horns of the crab and lobster. This hollowess, in our author's opinion, is to receive the sound communicated to the extremities of the antennæ by the repercussion of the air affected by any noise, and convey it, by means of the joints, from one to another, till it arrives in that lessened degree of tone best suited to the timid nature of the animal. In this circumstance there may be many variations in point of perfection in those organs: the strength, utility, and degree of power in receiving sound being proportioned to the necessities of the animals, different in their nature and requisites. In most animals, the entrance to the auricular organ is patulous; but in this case the animal would suffer great inconvenience from such an organisation, as the organ would often be clogged with dirt, &c.

It has also appeared dubious if they have the sense of smell, no organ being found in them adapted to that purpose: and although it was evident they had a perception of agreeable and fetid effluvia, it was thought to be in a manner altogether unknown to us. Mr Barbut is of opinion that the organs of smell reside in the palpi or feelers. Many insects have four and some six, two of which are in general cheliform, in order to assist the insect in conveying its food to its mouth. It may be likewise observed, that the palpi are in continual motion; the animal thrusting them into every kind of putrid or other matter, as a hog would do his nose, smelling and searching after food. Insects which apparently do not possess palpi or spiral tongues, have undoubtedly some organ concealed within the mouth analogous to them in function and utility; the fleshy proboscis of the fly is thrust into every substance in which the animal expects to find food; and when it is extended, nearly in the middle are situated, in our author's opinion, two upright palpi, which, no doubt, perform in their turn some office, perhaps that of smell.

Eyes, Antennæ, &c. of Insects.

Many insects have no tongue, nor make any sound with their mouth; but for this purpose some use their feet, others their wings, and others some elastic instrument with which they are naturally furnished.

EYES. Most insects have two; but the gryinus has four, the scorpion six, the spider eight, and the scolopendra three. They have no eye-brows, but the external tunic of their eyes is hard and transparent like a watch-glass; their eyes have no external motion, unless it be in the crab. They consist for the most part of one lens only; but in those of the butterfly, dipteræ, and many of the beetles, they are more numerous. Pugett discovered 17,325 lenses in the cornea of a butterfly, and Lieuwenhoek 800 in a fly.

ANTENNÆ. Of these there are in general two (unless four are allowed to some kind of crabs), and placed on the fore-part of the head: they are peculiar to insects; and are plainly distinguishable from the tentaculæ of the vermes, in being crustaceous; and from the palpi of insects, which are more numerous, placed near the mouth, and are sometimes wanting. As the antennæ are of great moment in distinguishing the various kinds of insects, we shall enumerate and explain the several different forms of them.

Setacæ, are those which grow gradually taper towards the extremity.

Filiformes, such as are of the same thickness throughout.

Moniliformes, are filiform, like the preceding, but consist of a series of round knobs, like a necklace of beads.

Clavatæ, such as gradually increase in size toward the extremity.

Capitatæ, are *clavatæ*, but have the extremity somewhat round.

Fissiles, are *capitatæ*; but have the capitulum, or knob, divided longitudinally into three or four parts, or laminæ, as in the scarabæi.

Perfoliatæ, are also *capitatæ*; but have the capitulum horizontally divided, as in the dermeistes.

Pectinatæ, so called from their similitude to a comb, tho' they more properly resemble a feather, as in the moths and elateres. This is most obvious in the male.

Aristatæ, such as have a lateral hair, which is either naked or furnished with lesser hairs, as in the fly: *Breviores*, those which are shorter than the body; *longiores*, those which are longer than the body; *mediocres*, those which are of the same length with the body; all three of which varieties are distinguishable in the cerambyces.

PALPI, or *Feelers*, resemble filiform, articulated, moveable antennæ. They are most commonly four in number, sometimes six; they are sufficiently distinguished from antennæ, in being naked, short, and always placed at the mouth.

Os, the *Mouth*, is generally placed in the anterior part of the head, extending somewhat downwards. In some insects, it is placed under the breast, as in the chermes, coccus, cancer (crab), and curculio.

ROSTRUM, or *Proboscis*, is the mouth drawn out to a rigid point: in many of the hemiptera class it is bent downward toward the breast and belly, as in the cicada, nepa, notonesta, cimex (bug), aphid, and remarkably so in some curculiones.

MAXILLÆ, the *Jaws*, are two in number, sometimes

four, and at other times more; they are placed horizontally; the inner edge of them in some insects is serrated, or furnished with little teeth.

LINGUA, the *Tongue*, in some insects is taper and spiral, as in the butterfly; in others it is fleshy, resembling a proboscis, and tubular, as in the fly.

LABIUM *superius*, the *upper Lip*, is situated above the jaws; as in the scarabæus and gryllus.

STEMMATA, or *Crown*, are three smooth hemispheric dots, placed generally on the top of the head; as in most of the hymenoptera, and others.

II. TRUNCUS, the TRUNK, is that part which comprehends the breast or thorax: it is situated between the head and abdomen; and has the legs inserted into it, that its parts may be distinctly determined. It is divided into *thorax*, *scutellum*, and *sternum*.

THORAX, the *Thorax*, is the back part of the breast; and is very various in its shape. It is called *dentatus*, when its sides are armed with points; *spinatus*, when its back is furnished with them, as in the cerambyx; and *marginatus*, when its margin is laterally dilated, as in the silpha and cassida.

SCUTELLUM, or *Escutcheon*, is the posterior part of the thorax: it is frequently triangular; and appears to be divided from the thorax by an intervening suture, as in most of the coleoptera.

STERNUM, the *Sternum*, is situated on the inferior part of the thorax; it is pointed behind in the elateres, and bifid in some of the dytisci.

III. ABDOMEN, the ABDOMEN is in most insects distinct from the thorax; it is the posterior part of the body of the insect; and is composed of a number of annular segments, which serve occasionally to lengthen or shorten it, and to contain the organs of chylicification, &c.

SPIRACULA, are little holes or pores, placed singly on each side of every segment of the abdomen: thro' these the insect breathes; and if oil be applied so as to stop them up, it proves fatal to most of them.

TERGUM, the *Back*, is the superior part of the abdomen.

VENTER, the *Belly*, is the inferior part.

ANUS, is the posterior part of the abdomen, perforated for the evacuation of the excrement. This part also frequently contains the organs of generation.

IV. ARTUS, the LIMBS or EXTREMITIES, are the various instruments of motion.

PEDES, the *Legs*, are generally fix. There is an exception to this, however, in the class Aptera, many of which have eight; as acarî (mites), phalangii, most of the aranei, (spiders) scorpiones, (scorpions) and cancri (crabs). The oniscus has 14, and the Iuli and scolopendri still more.

The first joint of the leg, which is generally thickest, is called *femur*; the second, which is generally of the same size throughout, *tibia*; the third, which is jointed, is distinguished by the name of *tarsus*; and the last, which in most insects is double, by that of *unguis*. The legs of insects, in general, are named from the various motions they produce: *Cursorii*, from that of running, which are the most numerous;

fat-

&c. *saltatorii*, from that of leaping; *natatorii*, from that of swimming, &c.—In the *saltatorii*, the thighs are remarkably large, by which means they are able to leap to a considerable distance, as in the gryllus, (grasshopper), &c. In those of the *Natatorii*, the feet are flat, and edged with hairs, which answer the purpose of oars in assisting them to swim, as in the dytiscus.—*Mutici*, are such feet as have no claws.—*Chelæ*, or claws, are the fore-feet enlarged towards their extremities, each of which is furnished with two lesser claws, which act like a thumb and finger; as in the crab.

Alæ, *Wings*, the instruments which enable them to fly. These are membranous, and undivided, except in the instance of the phalænæ alucitæ, in which they are in part divided. Most insects have four; the diptera-class, and the coccus, however, have two only.

The wing is divided into its superior and inferior surfaces: its anterior part in a butterfly, is that towards the anterior margin, or next to the head; its posterior part, that towards the anus; its exterior part, that towards the outer edge; and the interior, that next the abdomen.

They are called *plicatiles*, when they are folded at the time the insect is at rest, as in the wasp; opposite to these are the *plane*, which are incapable of being folded.

Erectæ, such as have their superior surfaces brought in contact when the insect is at rest; as in the ephemeræ, libellula puella and virgo, and papilionæ (butterflies.)

Patentes, which remain horizontally extended when the insect is at rest; as in the phalænæ geometræ, and most of the libellulæ.

Incumbentes, such as cover horizontally the superior part of the abdomen when the insect is at rest.

Deflexæ, are incumbentes, but not horizontally, the outer edges declining toward the sides.

Reversæ, are deflexæ, with this addition, that the edge of the inferior wings projects from under the anterior part of the superior ones.

Dentatæ, in which the edge is serrated, or scolloped.

Caudatæ, in which one or more projections in the hinder wings are extended into processes.

Reticulatæ, when the vessels of the wings put on the appearance of network, as in the hemerobius perla; the two anterior wings generally become superior, and the posterior ones inferior, in moths, when their wings are closed; but the anterior wings are called *primary*, and the inferior ones *secondary*, in butterflies, as they cannot with propriety be called *inferior* when the wings are erect.

Colores, the colours, these are self-apparent; but according to their several shapes, they take the different names of *punctæ*, dots; *maculæ*, spots; *fasciæ*, bands, which frequently run across and sometimes surround the edge of the wings; *Strigæ*, streaks, which are very slender fasciæ; and *lineæ*, lines, which are longitudinally extended.

Ocellus, is a round spot, containing a lesser spot of a different colour in its centre.

Stigmata, another term lately introduced by Linnaeus, signifies the spot, or anastomosis, in the middle

of the wing near the anterior margin; it is conspicuous in most of the hymenoptera and neuroptera, and even in the coleoptera. The fingle or double kidney-shaped spot, situated in the same part of the anterior wings, and frequently occurring in the phalænæ paganeæ, is distinguished likewise by the name of *stigma*.

Elytra (in the singular number elytron.) The upper wings, which are of a hard substance, in some degree resembling leather, and which in most insects are of a very hard texture, but in others flexible, are called *elytra*; their superior surface is generally convex, their inferior one concave. When the insect flies, they are extended; and thus when it rests, closing together, and forming a longitudinal suture down the middle of the back, as in the coleoptera.

They are of various shapes. *Abbreviata*, when shorter than the abdomen. *Truncata*, when shorter than the abdomen, and terminating in a transverse line. *Fassiziata*, when of equal or greater length than the abdomen, and terminating in a transverse line. *Serrata*, when the exterior margin towards the apex is notched or serrated, as in some of the buprestes. *Spinosa*, when their surface is covered with sharp points or prickles. *Scabra*, when their surface is so uneven as to grate against the fingers. *Striata*, when marked with slender longitudinal furrows. *Porcata*, when with elevated longitudinal sulci or ridges. *Sulcata*, when these ridges are concave. *Hemelytra*, when the superior wings are of a middle substance betwixt leather and membrane; either totally so, as in the grylli; or partially so, as in the cimices, nepæ, and notonectæ: These are commonly distinguished by the name *hemiptera*.

Halteres, poisers, (a term also introduced by Linnaeus), are little heads placed on a stalk or peduncle, most frequently under a little arched scale. They are found only in the class diptera, and appear to be nothing more than the rudiments of the hinder wings.

CAUDA, the Tail, in most insects is,

Simplex, simple, capable of being extended, and again drawn back at pleasure. In the crab and scorpion, however, it is

Elongata, elongated, or lengthened out.

Setacea, bristle-shaped, or taper; as in the raphidia.

Trifida, consisting of three bristles; as in the ephemeræ.

Furcata, being forked, as in the podura.

Forcipata, resembling a pair of forceps; as in the forficula.

Foliosa, resembling a leaf; as in the blatta, grylli, and some species of cancri.

Teliferæ, such as are armed with a dart or sting; as in the scorpion and panopæa.

Aculeus, an instrument with which they wound, and at the same time infill a poison; with such the bee, wasp, scorpion, &c. are furnished.

EXPLANATION of PLATE CCCXVIII. upper Compartment.

Fig. I. ANTENNÆ PECTINATÆ, or feather'd; as in the phalænæ, moths.

2. ——— PERFOLIATÆ, or perfoliated; as in the dermestes and dytiscus.

3. ——— FISSILES, or fissile, divided into laminae

- minæ at the extremity, as in the *scarabæi*, beetles.
4. ANTENNÆ CLAVATÆ, or club-shaped, as in the *papilio*, butterfly.
 5. ——— MONILIFORMES, like a necklace of beads; as in the *chrysolæla*.
 6. ——— SETACÆ, setaceous, or bristle-shaped; as in many of the *phalænæ*.
 7. ——— ARISTATÆ, furnished with a lateral hair, as in the *ffy*.
 - 8 9. *a* Caput, the head.
b Palpi, or feelers.
c Antennæ, or horns.
d Oculi, the eyes.
e Thorax.
f Scutellum, or escutcheon.
g Pectus, or breast.
h Sternum, or breast-bone.
i Abdomen, and its segments.
k Anus.
l Elytra, or shells.
m Membranous wings.
n Pedes, or feet, which are natatorii.
 10. *o* Femur, or thigh.
p Tibia, or leg.
q Tarsus, or foot.
r Unguis, or claw.
 11. *a* The anterior part of the wing.
b The posterior part.
c The exterior part.
d The interior part.
e The margin.
f The disk, or middle.
g Oculus, or eye.
 - 12, 13, 14, 15. Represent the insect in its egg, caterpillar, pupa, and perfect state.

SECT. II. Of the SEXES of INSECTS.

THE same difference of sex exists in insects as in other animals, and they even appear more disposed to increase their species than other animals; many of them, when become perfect, seeming to be created for no other purpose but to propagate their species. Thus the silk-worm, when it arrives at its perfect or moth-state, is incapable of eating, and can hardly fly: it endeavours only to propagate its species; after which the male immediately dies, and the female as soon as she has deposited her eggs.

In many insects, the male and female are with difficulty distinguished; and in some they differ so widely, that an unskilful person might easily take the male and female of the same insect for different species; as for instance, in the *phalæna humuli*, *pinaria*, *russula*; each sex of which differs in colour. This unlikeness is still more apparent in some insects, in which the male has wings and the female none; as in the *coccus*, *lampyræ*, *phalæna antiqua*, *brumata*, *lichenella*. And as most insects remain a long while in copulation, as we may see in the tipula and silk-worm, the winged males fly with the wingless females, and carry them about from one place to another; as in the *phalæna antiqua*. It is, however, no certain rule, that when one insect of the same species is found to have wings, and the other to be without, the former must necessarily be

the male, and the latter the female. The aphides, for instance, are an exception; and besides these, individuals of both sexes, and of the same species, are found without wings, as the *carabi majores*, *tenebriones*, *meloes*, *cimices*. The *gryllus pedestris* is likewise destitute of wings; and might have passed for a *gryllus* in its pupa state, had it not been seen in copulation; for it is well known that no insect can propagate its species till it arrives at its last or perfect state.

“Pleraque insectorum genitalia sua intra anum habent abscondita, et penes solitarios, sed nonnulla penem habent bifidum: Cancræ autem et Araneæ geminos, quem admodum nonnulla amphibia, et quod mirandum in loco alieno, ut Cancræ, sub basi caudæ. *Araneus* mas palpos habet clavatos, qui penes sunt, juxta us utrinque unicum, quæ clavæ sexum nec speciem distinguunt; et femina vulvas suas habet in abdomine juxta pectus. Heic vero si unquam vere dixeris, “Res plena timoris amor:” si enim proci in auspicio accesserit, femina ipsum devorat; quod etiam fit, si non statim se retraxerit. Libellula femina genitale suum sub apice gerit caudæ, et mas sub pectore; adeo ut cum mas collum femina forcipè caudæ arripit, illa caudam suam pectori ejus adplicet, sicque peculiari ratione connexæ volunt.”

Besides those of the male and female, a third sex exists in some insects which we call *neuter*: As these have not the distinguishing parts of either sex, they may be considered as eunuchs or infertile.

We know of no instance of this kind in any other class of animals, nor in vegetables, except in the class Syngenesiæ, and in the *Opulus*. This kind of sex is only found among those insects which form themselves into societies, as bees, wasps, and ants: and here these kind of eunuchs are real slaves, as on them lies the whole business of the economy; while those of the other sex are idle, only employing themselves in the increase of the family. Each family of *Bees* has one female only (called the *queen*), many males, and an almost innumerable quantity of neuters. Of those, the neuters (whose antennæ have 11 joints) do the working part; they extract and collect honey and wax, build up the cells, keep watch, and do a variety of other things. The males, whose antennæ consist of 15 joints, do no work; they serve the female once, and that at the expense of their lives; they may be considered in the light of a set of parasites, or cecidæ; but as soon as their business of impregnation is over, they are expelled by their servants the neuters, who now shake off the yoke, but yet pay all due respect to their common mother the queen. The same economy nearly takes place in *Wasps*, where the young females, which are impregnated in the autumn, live through the winter, and in the spring propagate their species; but the queen, together with all the males, perish in the winter. Among *Ants*, the neuters form a hill in the shape of a cone, that the water may run off it, and place those which are in the pupa state on that side of it which is least exposed to the heat of the sun. At a considerable distance from these are found the habitations of the males and females, to whom the most ready obedience is yielded by the neuters, till a new offspring succeeds, and then they oblige them to quit their habitations. But those ants which live entirely under ground,

ground, provide better for themselves in this respect : for a little before their nuptials, they quit their habitation of their own accord, and after swarming in the manner of bees, they copulate in the air ; and each retiring to some new habitation, founds a new family.

No *hermaphrodites* have as yet been discovered among insects. There is something very singular, however, in the propagation of the aphides. A female aphid once impregnated, can produce young, which will continue to produce others without any fresh impregnation, even to the fifth progeny ; afterwards a new impregnation must take place. See *APHIS*, (*Encycl.*)

The male insects, like male hawks, are always smaller than the females.

In the propagation of their species they are remarkably careful ; so that it is with the greatest difficulty that flies are kept from depositing their eggs on fresh meat, the cabbage butterfly from laying them on cabbage, and other insects from depositing them in the several places peculiar to each. The scarabæus pilularius and carnisæx, are deserving of our attention, as they afford a mutual assistance to each other : for when the female has laid her eggs in a little ball of dung, the males, with their feet, which are axiform, assist the female to roll it to some suitable place ; as Aristotle and Pliny formerly, and Loeffing has lately observed.

It is very wonderful to observe, that in the coccus and oniscus, the female has no sooner brought forth her young, than she is devoured by it ; and that the sphæx should be able so readily to kill the caterpillar of a moth, then bury it in the earth, and there deposited her eggs in it. Nor can we without admiration behold the same species of aphid, which was viviparous in the summer, become oviparous in the autumn.

Almost innumerable examples might be brought of the singularities in the eggs of insects ; we shall, however, only mention those of the hemerobius, which are deposited on a footstalk ; those of the phalæna neutria, which are placed regularly in a ring round the branch of some tree ; and the compound eggs of the blatta.

SECT. III. *Metamorphoses of Insects.*

THERE are no insects, except those of the aptera class, but what are continually undergoing some transformation. Insects change first from the (ovum) egg, into the (larva) caterpillar or maggot ; then into the (pupa) chrysalis ; and lastly into the (imago) fly or perfect state. During each of those changes, their appearance differs as much as night and day.

The insect, as soon as it came out of the egg, was by former entomologists called *eruca* ; but as this is synonymous with the botanic name *gysymbrium*, it was changed by Linnæus for the term *larva*, a name expressive of the insect's being, in this state, as it were masked, having its true appearance concealed. Under this mask or skin the entire insect, such as it afterwards appears when perfect, lies concealed, enveloped only in its tender wings, and putting on a soft and pulpy appearance ; inasmuch that Swammerdam was able to demonstrate the butterfly with its wings to exist in a caterpillar, though it bore but a faint resemblance to its future perfection. The insect, therefore, in this state, undergoes no other alteration but the change of its skin.

The larvæ are, for the most part, larger than the insect when perfect, and are very voracious. The caterpillar of the cabbage-butterfly eats double what it would seem to require from its size ; but its growth is not adequate to its voracity.

Pupa. The insect in this state was formerly called *chrysalis*, or *aurelia* : but as the appearance of gilding is confined to a few butterflies only, the term of *pupa* has been adopted in its stead ; because the lepidoptera, especially, resemble an infant in swaddling clothes ; and in this state all, except those of the hemiptera class, take no nourishment.

Imago, is the third state. This name is given by Linnæus to this third change, in which the insect appears in its proper shape and colours ; and as it undergoes no more transformations, it is called *perfect*. In this state it flies, is capable of propagating its species, and receives true antennæ ; which before, in most insects, were scarce apparent.

As the shape of the Pupa is different, in different classes of insects, it assumes different names ; thus it is called

Coarctata, when it is round, and as it were turned, without the least resemblance of the structure of the insect ; as in the diptera.

Obtecta, when it consists as it were of two parts, one of which surrounds the head and thorax, and the other the abdomen.

Incompleta, when they have wings and feet, but are not capable of moving them ; as in most of the hymenoptera.

Semicompleta, in which they walk or run, but have only the rudiments of wings.

Completa, in which they immediately obtain the perfect form of the insect, without undergoing any more change ; as in those of the aptera class, except only the flea. The bed bug also belongs to this class.

The spider undergoes frequent transformations, though only in the colour of its skin. The crustaceous insects, as crabs, lobsters, &c. yearly cast their shells, as their growth would otherwise be impeded.

The scolopendri, when young, have fewer feet than when they are full grown.

All insects, as soon as they undergo the third change, are arrived at their full growth ; nor do we find any difference in the size of the same species of insect in the same countries, unless, during its caterpillar state, it has not had a sufficiency of proper food.

SECT. IV. *Classification of Insects.*

As insects are endowed with the various powers of creeping, flying, and swimming, there is scarce any place, however remote and obscure, in which they are not to be found. The great confusion which appeared to the ancients to arise from their number, made them never dream of reducing them to any system. Swammerdam, that indefatigable inquirer into nature, observed that their metamorphoses were divided by nature into several states or orders. Their external appearance also carried with it some mark of distinction ; so that entomologists called all those of the coleoptera class, *Scarabæi* (beetles) ; those of the lepidoptera, *Papilionæ* ; and those of the gymnoptera class that had two wings only, *Muscæ* (flies) ; those of the bee class that had four wings, were called *Apæ* (bees). No far-

farther progress was made in the systematic part of this science till the time of Linnæus. He was the first that undertook to determine the genera, and assign them their proper characters, in the *Systema Nature*; and thus reduced this science to a systematic form. This system, in subsequent editions, was considerably enriched and amended by him, inasmuch that the science of insects now shines forth in its full lustre. He it was who first instituted natural orders, and reduced them into genera by expressive names; determined an infinite number of species in the *Fauna Suecica*, and *Musæum Regiæ*; collected with incredible pains the synonymous names of the various authors who had written on them; and lastly, added their descriptions, and the places in which they were to be found. So that the system of this illustrious author will lead any person, without the assistance of a master, for the most part, easily to ascertain the name of any insect he may meet with. Before his time scarce any more than 200 insects were known; whereas, in the last edition of his system, he has determined the names of nearly 3000 distinct species.

CLASSES. The Linnæan classes of insects are seven; as enumerated in Zoology, and under the article INSECTS, (*Encycl.*) which see.

ORDERS. These classes are again subdivided into different orders: for which see the articles ZOOLOGY and INSECT, (*Encycl.*) and Plate CLIV.

GENERA. To insert here the characters of all the different genera which may be found in Linnæus's *Syst. Nat.* would be unnecessary. It will be sufficient to enumerate some new genera mentioned by the most modern systematic writers, that, by being acquainted with the subtle distinctions on which they are built, the student may avoid running into confusion. It is among the moderns only that genera of this kind are to be met with, and new names given them. To remove this difficulty, we shall first enumerate the names of those authors which are synonymous with those of Linnæus.

New Genera of authors synonymous with those of Linnæus.

| <i>Linnæus's Names.</i> | <i>Names of other Authors.</i> |
|-------------------------|--------------------------------|
| Lucanus | <i>Platyceros</i> |
| Hister | <i>Attelabus</i> |
| Byrrhus | <i>Anthrenus Cistela</i> |
| Mylabris | <i>Laria Scop.</i> |
| Attelabus | <i>Clerus</i> |
| Silpha | <i>Peltis</i> |
| Bruchus | <i>Mylabris</i> |
| Pinus | <i>Byrrhus</i> |
| Chrysomela | <i>Galericula</i> |
| Hispæ | <i>Crispæris</i> |
| Cantharis | <i>Cicindela</i> |
| Buprestis | <i>Cucujus</i> |
| Carabus | <i>Buprestis</i> |
| Myrmelcon | <i>Formicaleo</i> |
| Sirex | <i>Urocero</i> |

New genera of authors.

| | |
|---------------------|---------------------------------------------------|
| <i>Copris.</i> | <i>Scarabæus absque scutello</i> |
| <i>Bostriculus.</i> | <i>Dermestes capecinus</i> |
| <i>Cistela.</i> | <i>Byrrhus Pilula</i> |
| <i>Rhinomancer.</i> | <i>Attelabus rostro producto sere Curculionis</i> |
| <i>Anthribus.</i> | <i>Silpha</i> |

| | |
|-----------------------|----------------------------------------------|
| <i>Bruchus.</i> | <i>Pinus Fur ob spinas thoracis</i> |
| <i>Melontha.</i> | <i>Chrysomela cylindrica</i> |
| <i>Altica.</i> | <i>_____ saltatoria</i> |
| <i>Diaperis.</i> | <i>_____ fungorum</i> |
| <i>Pyrochora.</i> | <i>Cantharis</i> |
| <i>Telephorus.</i> | <i>Cantharis</i> |

| <i>Notaxis.</i> | <i>Meloë Monoceros</i> |
| <i>Prionus.</i> | <i>Cerambyx thoracis margine denticulato</i> |
| <i>Stenocoris.</i> | <i>Leptura thoracis spinosa</i> |
| <i>Hydrophilus.</i> | <i>Dytiscus antennis clavatis</i> |
| <i>Mylabris.</i> | <i>Necydalis minor</i> |
| <i>Acridium.</i> | <i>Gryllus Muticus</i> |
| <i>Locusta.</i> | <i>_____ Tettigonia</i> |
| <i>Tettigonia.</i> | <i>Cicada</i> |
| <i>Corixa.</i> | <i>Notonecta</i> |
| <i>Nauocoris.</i> | <i>Nepa</i> |
| <i>Perla.</i> | <i>Hemerobius cauda bifida</i> |
| <i>Libelluloides.</i> | <i>Myrmelcon antennis capitatis</i> |
| <i>Crabro.</i> | <i>Tenthredo antennis clavatis</i> |
| <i>Pterophorus.</i> | <i>Phalæna Alucita</i> |
| <i>Bibio.</i> | <i>Tipula thoracis spinosa</i> |
| <i>Stomoxoides.</i> | <i>Aphis buccæ inflata</i> |
| <i>Stratiomymus.</i> | <i>Musca</i> |
| <i>Nemotelus.</i> | <i>Musca</i> |
| <i>Velucella.</i> | <i>Musca.</i> |

These genera appear to be in a great measure like those which were introduced into botany by the followers of Rivinus. Paying too little regard to nature, they dissipated natural genera, on account of the most trifling distinctions. This made their continuance in the science of very short duration; our business here is not to suppose, but to examine, what nature will allow of, and what she will not. Knowledge of this kind, built on opinion only, will not stand. We are therefore to look into the science with great accuracy; and the larva of the insect, its manner of changing, and other things of moment, are to be known, before we presume to form a new genus.

Coining of new names, and changing of one old one for another, has been the source of the greatest confusion. Thus, in order to reduce the cicindela and carabus to the same genus, *buprestis* has been adopted for the generic name; but as that genus had long ago received a very different application, it was changed for that of *cucujus*.

Again, that the official cantharides might be ranged among the cerambyces, the cantharides have been removed from the genus of meloë (to which they naturally belong), and referred to the genus of cicindela, obtaining thus a new name. And so of many others.

Thus also, to mention no more, how needless and rash was it to separate the acridium and locusta from the genus of gryllus, the crabro from the tenthredines, and the mylabris from the necydalis!

TRIVIAL NAMES. The trivial names placed under their respective genera will occasion little or no controversy; they are current like money, and of the same utility as the proper names of men, Peter or Paul, &c. Insects living on vegetables should receive their names from the particular plants on which they mostly feed, as they are preferable to all others. Thus the names of the *phalæna mori*, &c. are excellent; and when we are able to give such to insects, the old ones are to be discarded.

discarded. But we are to be cautious of not being too hasty in our judgment in this respect; as insects, when they cannot get their favourite food, will often eat other plants. Thus the silk-worm, for want of mulberry leaves, will eat those of lettuce, though it will not thrive so well on them.

Many other instances of the invention of trivial names will be met with in the *Systema Naturæ*, particularly among the butterflies and moths. To prevent confusion from the great number of species which constitute the genus of *phalæna*, they are distributed into sections, and distinguished by the terms of *bombyces*, *noctuæ*, *geometræ*, *tortrices*, *pyralides*, *tineæ*, and *alucitæ*. The *bombyces* and *noctuæ*, which are so much alike, that the females of the *bombyces* are with great difficulty distinguished from the *noctuæ*, are named promiscuously.

All those of the *geometræ* have their names terminating in *aria* and *ata*, according as their antennæ are setaceous or pectinated. The *tortrices*, in *aria*; the *pyralides*, in *alis*; the *tineæ*, in *ella*; and the *alucitæ*, in *dactyla*: so that it is evident from the termination itself to what section the insect is to be referred.

It were to be wished that similar institutions could be formed throughout the whole science, as here the name itself serves to distinguish the insect.

Butterflies are divided into sections, by the names of *Equites*, *Heliconii*, *Danai*, *Nymphalei*, and *Plebei*.

In such a multitude of butterflies, the greatest part of which are foreign and extra-european, and to whose food and manner of life we are utter strangers, it was impossible to give significant trivial names. Linæus, therefore, by way of simile, has taken the names of the *Equites* from the Trojan history. These consist, as it were, of two troops or bodies; of which one contains the fable, and as it were mourning nobles, having red or bloody spots at the basis of their wings. These receive names from the Trojan nobles; and as

Priam was king of Troy, the most splendid among these bear his name. The other body, ornamented with a variety of gay colours, are distinguished by the names of the Grecian heroes; and as in both armies there were kings as well as officers of an inferior rank, those elegant butterflies, whose hinder-wings resembled tails, were distinguished by some royal name. Thus when Paris is mentioned, (knowing from history that he was a Trojan, and of royal blood), I find him among those of the first section; that is, those of a fable colour, spotted in the breast with red, and having their hinder-wings resembling tails. When Agamemnon is named, I remember him to be a noble Greek, and find him among those nobles which have variegated and swallow-tailed wings. But when Nereus is spoken of, I readily know him to belong to the last section, with wings having no tails.

The second class, which contains the *Heliconii*, derive their names from the muses, as Urania. The names of the sons and daughters of Danaus are bestowed on the third section. And as these species are subdivided into two other sections, viz. the white and parti-coloured, the metaphor is so conducted, that the white ones preserve the names of the daughters of Danaus, and the parti-coloured ones those of the sons of Egyptus; so that it is evident from the name itself to what section the butterfly is to be referred.

The names of the fourth section, *Nymphalei*, are taken from various nymphs of antiquity; and those of the fifth section, *Plebei*, are selected from different men among the ancients whose names are worthy of remembrance: so that by this means a knowledge of the ancients may be interperfed, and this agreeable science be made doubly pleasing.

Those, therefore, who shall find new lepidoptera, and give them new names, will do well to follow this method, unless it be apparent what food the insect chiefly subsists on.

E P A

EPACTS, in chronology, the excesses of the solar month above the lunar synodical month, and of the solar year above the lunar year of twelve synodical months; or of several solar months above as many synodical months, and several solar years above as many dozen of synodical months.

The epacts, then, are either *annual* or *menstrual*. Menstrual epacts are the excesses of the civil or calendar month above the lunar month. Suppose, *e. gr.* it were new-moon on the 1st day of January; since the lunar month is 29 days 12^h 44' 3", and the month of January contains 31 days, the menstrual epact is 1 day 11^h 15' 57".

Annual epacts are the excesses of the solar year above the lunar. Hence, as the Julian solar year is 365 days 6^h, and the Julian lunar year 354 days 8^h 48' 38", the annual epact will be 10 days 21^h 11' 22"; that is, nearly 11 days. Consequently the epact of 2 years is 22 days; of 3 years, 33 days; or rather 3, since 30 days make an *embolismic* or intercalary month.

Thus the epact of 4 years is 14 days, and so of the rest; and thus, every 19th year, the epact becomes 30 or 0; consequently the 20th year the epact is 11 again; and so the cycle of epacts expires with the golden number, or lunar cycle of 19 years, and begins with the

E P A

fame, as in the following table:

| Gold. Num. | Epacts. | Gold. Num. | Epacts. | Gold. Num. | Epacts. |
|------------|---------|------------|---------|------------|---------|
| 1 | XI | 7 | XVII | 13 | XXIII |
| 2 | XXII | 8 | XXVIII | 14 | IV |
| 3 | III | 9 | IX | 15 | XV |

Again, as the new moons are the same, that is, as they fall on the same day every 19 years, so the difference between the lunar and solar years is the same every 19 years. And because the said difference is always to be added to the lunar year, in order to adjust or make it equal to the solar year; hence the said difference respectively belonging to each year of the moon's cycle is called the *epact of the said year*, that is, the number to be added to the said year, to make it equal to the solar year; the word being formed from the Greek *επαγειν*, *induco*, *intercolo*.

Upon this mutual respect between the cycle of the moon and the cycle of the epacts, is founded this rule

Ephemeræ. for finding the Julian epact, belonging to any year of the moon's cycle. Multiply the year given of the moon's cycle into 11; and if the product be less than 30, it is the epact sought; if the product be greater than 30, divide it by 30, and the remainder of the dividend is the epact. For instance, I would know the epact for the year 1712, which is the third year of the moon's cycle. Wherefore 3 is the epact for 1712; for $11 \times 3 = 33$, and 33 being divided by 30, there is left 3 of the dividend for the epact. But the difference of the Julian and Gregorian years being equal to the excess of the solar above the lunar year, or 11 days, it happens that the Gregorian epact for one year is the same with the Julian epact for the preceding year.

EPHEMERA, (Encycl.) These flies, who take their name from the shortness of their life, are distinguished into several species. Some live several days, others do not take flight till the setting of the sun, and live not to see the rising of that luminary. Some exist but one hour, others but half that time; in which short period they comply with the call of nature. With respect to those that live several days, there is a peculiarity observed, incident to themselves alone.

Plate
CCCXIII.

Barb's
Insects.

They have to cast off one slough more, an operation which sometimes takes 24 hours to complete. To bring this about, they cling fast to a tree. The ephemeræ, before they flutter in air, have in some manner been fishes. They remain in the states of larva and chrysalis for one, two, or three years. The chrysalis only differs from the larva by there being observable on its back cases for wings. Both have on their sides small fringes of hair, which, when put into motion, serve them as fins. Nothing can be more curious than the plying of those little oars in the water. Their abdomen is terminated, as well as in their state of flies, by three threads. These larvae scoop themselves out dwellings in the banks of rivers; and they are small tubes made like siphons, the one serving for an entrance, the other affording them an outlet. The banks of some rivers are often perforated with them. When the waters decrease, they dig fresh holes lower down, in order to enjoy their element the water. The season and hour when the chrysalids of the different species of the ephemeræ turn into flies, maintain a kind of regularity. The heat, the rise or fall of the waters, accelerate, however, or postpone their final display. The ephemeræ of the Rhine appear in the air two hours before sunset. These flies are hatched almost all at the same instant in such numbers as to darken the air. The most early of those on the Marne and Seine in France do not begin to fly till two hours after the setting of the sun, towards the middle of August. They are seen fluttering and sporting on the brink of their tomb. The glare of light attracts them, round which they perform a thousand circles with amazing regularity. Their coming together for the purpose of generation can only be surmised, the shortness of their life requiring that all its functions should be proportionable in their duration. Some naturalists have been of opinion, that the males impregnated the eggs after the manner of fishes. The females, by the help of the threads of their tail and the flapping of their wings, support themselves on the surface of the water, and in that almost upright situation drop their eggs in clusters. One single female will lay 700

or 800 eggs, which sink to the bottom. The larvæ that escape from the voraciousness of the fishes, set about the construction of habitations to shelter them from every kind of danger. When the flies have propagated, they are seen to die and fall by heaps. The land and water are strewn with them to a considerable thickness. The fishermen consider these multitudes of destroyed insects as manna for the fishes.

EPHORI, (Encycl.) Some authors deny that the ephori were established by Lyncurgus, dating their origin 130 years after the time of that legislator. Thus Plutarch, in his Life of Cleomenes, ascribes their institution to Theopompus king of Sparta; which is also confirmed by the authority of Aristotle.

EPIC. For POETRY, chap. ii. read Part II. chap. i.
EPILOBIUM, (Encycl.) An infusion of the leaves of the angustifolium, or rosbay willow-herb, has an intoxicating quality, as the inhabitants of Kamtschatka have learned. These people also eat the white young shoots which creep under the ground, and have a sort of ale brewed from the dried pith of it. The down of the seeds has been lately manufactured by mixing it with cotton or beaver's hair.

EPITHEM. For 1015, read 1026.

ERYTHRINA, (Encycl.) Of the wood of this tree the inhabitants of Malabar make sheaths for swords and knives. They use the same, together with the bark, in washing a sort of garment which they call *jara-jas*; and make of the flowers, the confection *caryl*. The leaves pulverised and boiled with the mature *nux Indica*, or coccoa-nut, consume venereal buboes, and ease pains in the bones; bruised and applied to the temples, they cure the cephalæ and ulcers; mixed with the sugar called *jagra*, they mitigate pains in the belly, especially in women; and the same effect follows from the use of the bark leavigated with vinegar, or swallowing the kernel stripped of its red pellicle. The juice of the leaves taken with oil fergelim, mitigates venereal pains; drank with an infusion of rice, it stops fluxes; made into a cataplasm with the leaves of beteiera, it destroys worms in old ulcers; and worked with oil, it cures the psoa and itching.

Ray.

ESCHEAT, (Encycl.) Escheat is one of the consequences of tenure in chivalry. See FEODAL System, KNIGHT-Service, and TENURE. It is the determination of the tenure, or dissolution of the mutual bond between the lord and tenant, from the extinction of the blood of the latter by either natural or civil means: if he died without heirs of his blood, or if his blood was corrupted and stained by commission of treason or felony; whereby every inheritable quality was entirely blotted out and abolished. In such cases the land escheated or fell back to the lord of the fee; that is, the tenure was determined by breach of the original condition, expressed or implied in the feudal donation. In the one case, there were no heirs subsisting of the blood of the first feudatory or purchaser, to which heirs alone the grant of the feud extended: in the other, the tenant, by perpetrating an atrocious crime, showed that he was no longer to be trusted as a vassal, having forgotten his duty as a subject; and therefore forfeited his feud, which he held under the implied condition that he should not be a traitor or a felon. The consequence of which in both cases was, that the

Ephori
Escheat.

gift, being determined, resulted back to the lord who gave it.

ESCHARA, in natural history, the name of a species of coralline, &c. the characters of which are these: they are of a stony or coral-like hardness, and resemble a woven cloth in their texture; and the microscope informs us, that they consist of arrangements of very small cells, whose surfaces appear much in that form. Linnaeus makes it a species of millepora, in the class of lithophytes. See Plate CCCXVI. fig. 9. 10.

The narrow-leaved hornwrack, fig. 9. divides as it rises, into narrow leaves made up of regular rows of oblong square-shaped cells placed alternately by each other, and opposite to an equal number on the other side of the leaf, like an honeycomb: from these leaves proceed other still smaller foliaceous ramifications, many of which seem to be connected at the lower part by tubuli; as in the corallines; by which means they can ply to and fro more freely in the water.—*f.* Gives the natural appearance of this coralline. *E* represents two leaves with their tubuli and cells magnified. *E* 1 is a cross section of one of the leaves at *E*, showing the partition and inner form of their cells.

The broad-leaved hornwrack, fig. 10. when fresh taken out of the sea is of a spongy soft texture and smells very fishy; but when it has lain for some time on the shore, it becomes stiff and horny, like some sort of withered leaves. Both surfaces, when examined by glasses, appear to be covered with cells; and, when a piece of it is cut across, one may discover the thin membrane that serves as a base to the cells of each surface. The form of the cells is very remarkable, each one being arched at the top, and contracted a little at the lower part of the sides to make way for the arches of the two next adjoining cells; so that by this particular construction no room is lost. The entrance of the cells is immediately under the arch of each cell, and the walls of the cells seem to be fortified with spines. Jussieu discovered small polytes extending themselves out of these cells, which he has described in the memoirs of the Academy of Sciences 1742.—*f.* Gives the natural appearance of a leafy branch of this coralline. *F* is a part of a leaf magnified to show the superficial figure of the cells, and the manner in which they are disposed. *F* 1 shows a cross section of a leaf, and discovers the several partitions of the cells.

At the entrance of many of the cells a small testaceous body like a bivalve shell is discovered: *F* 2, the

figure of the cell, with the shell in it; it is of a transparent amber colour, so clear that one may see the dead animal through it, represented by the black spot.

ESTRAY, or **STRAY**, signifies any tame beast, as sheep, oxen, swine, and hories, or swans, found within a lordship, and not owned by any man; in which case being cried, according to law, in the church, and two market towns adjoining, if it be not claimed by the owner within a year and a day, it becomes the lord's of the soil where found. If the owner claims it within the year and day, he must pay the charges of finding, keeping, and proclaiming them; and he may seize it, without telling the marks, or proving his property, which may be done at the trial if contested. If the beast stray within the year to another lordship, the first lord cannot retake it. An estray must be fed and kept, uninjured, and without labour, till it is reclaimed, or the limited time expires.

EUPATORIUM, (*Encycl.*) See also *HEMP Agrimony*, (*Encycl.*)

EXERCISE, in military affairs, (*Encycl.*) See also *Words of Command*, (*Encycl.*)

EYE, (*Encycl.*) A new-born child shall be observed, perhaps, never to keep its eyes fixed on any one object, but continually changing from one to another, and if you put your hand before them, the child will not wink. Hence some have thought, that new-born infants have no sight: but this is a mistake; and the true reason why their eyes are in perpetual motion is, that they have not yet acquired the habit of examining one thing at once with their eyes: their not winking at the approach of the hand, arises from their want of experience how easily their eyes may be hurt; but in a few days they get the habit of winking, so that afterwards their eyes do it spontaneously at the approach of danger.—See a description of the eye and its adjacent parts, by J. Warner.

Artificial eyes are made of concave plates of gold, silver, or glass, and are stained so as to resemble the natural eye. They must, when fixed in the orbit, be taken out and cleaned every night, and replaced in the morning. If no more of a diseased eye is removed than what is preternaturally projected, or if enough is left to preserve the muscles unhurt, the artificial eye will have a little motion from the muscles that remain. If the eye does not fit well, it irritates and inflames the other eye; in which case lay it aside, until one can be had that fits better.

F.

FARTHING, a small English copper coin, amounting to one-fourth of a penny. It was anciently called *fourthing*, as being the fourth of the integer or penny.

FARTHING of Gold, a coin used in ancient times, containing in value the fourth part of a noble, or 20d. silver. It is mentioned in the stat. 9 Hen. V. cap. 7. where it is enacted, that there shall be good and just weight of the noble, half-noble, and farthing of gold.

FARTHING of Land seems to differ from *FARDING-deal*. For in a survey-book of the manor of West-Hampton in Devonshire, there is an entry thus: A. B. holds six farthings of land at 126 l. per ann. So that

the farthing of land must have been a considerable quantity, far more than a rood.

FAWKES (Francis), an ingenious poet, had his school-education at Leeds; from whence he was transplanted to Jesus-college, Cambridge, where he took the degrees in arts. Entering early into holy orders, he settled first at Bramham in Yorkshire, near the elegant seat of that name (Mr Lane's), which he celebrated in verse in 1745, in a 4to pamphlet anonymous. His first poetical publications were "Gawen Douglas's Description of May and Winter modernised." Removing afterwards to the curacy of Croynod in Surry, he recommended himself to the notice of

Feoffment. Archbishop Herring, then resident there on account of his health, to whom besides other pieces he addressed an Ode on his recovery in 1754, printed in Mr Doddley's Collection. In consequence, his Grace collated him in 1755 to the vicarage of Orpington with St Mary Cray, in Kent; and Mr Fawkes lamented his patron's death in 1757 in a pathetic Elegy styled *Aurelius*, first printed with his Grace's "Seven Sermons," in 1763. He married about the same time Miss Purrier of Leeds. In April 1774, by the late Dr Plumtree's favour, he exchanged his vicarage for the rectory of Hayes. He was also one of the chaplains to the Princess Dowager of Wales. He published a volume of Poems by subscription in 8vo, 1761; the "Poetical Calendar, 1763," and "Poetical Magazine 1764," in conjunction with Mr Woty; "Partridge-shooting, an Eclogue, to the Honourable Cha. Yorke, 1797," 4to, and a "Family Bible," with notes, in 4to, a compilation. But his great strength lay in translation, in which, since Pope, few have equalled him. Witness his fragments of Menander (in his Poems); his "Works of Anacreon, Sappho, Bion, Moschus, and Musæus," 12mo, 1760; his "Idylliums of Theocritus," by subscription, 8vo, 1767; and his "Argonautics of Apollonius Rhodius," by subscription also, (a posthumous publication, completed by the Reverend Mr Meen of Emanuel College, Cambridge), 8vo, 1780. He died August 26. 1777.

FEOFFMENT, (*Encycl.*) is a substantive derived from the verb, to enfeoff, *feoffare* or *infeudare*, "to give one a feud;" and therefore feoffment is properly *donatio feudii*. It is the most ancient method of conveyance, the most solemn and public, and therefore the most easily remembered and proved. And it may properly be defined, the gift of any corporeal hereditament to another. He that so gives, or enfeoffs, is called the *feoffor*; and the person enfeoffed is denominated the *feoffee*.

This is plainly derived from, or is indeed itself the very mode of, the ancient feudal donation; for though it may be performed by the word "enfeoff" or "grant," yet the aptest word of feoffment is "*do* or *dedi*." And it is still directed and governed by the same feudal rules; inasmuch that the principal rule relating to the extent and effect of the feudal grant, *tenor est qui legem dat feudo*, is in other words become the maxim of our law with relation to feoffments, *modus legem dat donationi*. And therefore as in pure feudal donations the lord, from whom the feud moved, must expressly limit and declare the continuance or quantity of estate which he meant to confer, *ne quis plus donasse presumatur, quam in donatione expresserit*; so, if one grants by feoffment lands or tenements to another, and limits or expresses no estate, the grantee (due ceremonies of law being performed) hath barely an estate for life. For, as the personal abilities of the feoffee were originally presumed to be the immediate or principal inducements to the feoffment, the feoffee's state ought to be confined to his person and subsist only for his life; unless the feoffor, by express provision in the creation and constitution of the estate, hath given it a longer continuance. These express provisions are indeed generally made: for this was for ages the only conveyance, whereby our ancestors went to create an estate in fee-simple, by giving the land to the

feoffee, to hold to him and his heirs for ever; though it serves equally well to convey any other estate of freehold.

But by the mere words of the deed the feoffment is by no means perfected: there remains a very material ceremony to be performed, called *livery of seisin*; without which the feoffee has but a mere estate at will. See **SEISIN**, (*Encycl.*)

FERETTO, (*Encycl.*) Another way of making feretto is as follows. Make a number of stratifications of plates of copper and white vitriol alternately in a crucible; which place on the floor of the glass furnace near the eye; and let it stand there three days; then take it out, and make a new stratification with more fresh vitriol; calcine again as before. Repeat this operation six times, and a most valuable feretto will be obtained.

FICUS, (*Encycl.*) That part of the history of the fig-tree, which for many ages was so enigmatical, and which nothing but the doctrine of the sexes of plants has completely cleared up, namely, the husbandry or *caprification*, as it is called, is more particularly worthy of attention, not only as a singular phenomenon in itself, but as it has furnished one of the most convincing proofs of the reality of the sexes of plants. Our limits will not allow us to detail this subject; in brief it is this: It is now known, that the flowers of the fig-tree are situated within a pulpy receptacle, which we call the fig, or fruit of this tree; of these receptacles, in the wild fig-tree, some have male flowers only, and others have male and female, both distinct, though placed in the same receptacle. In the garden, or cultivated fig, these are found to contain only female flowers; which are fecundated by means of a kind of gnat bred in the fruit of the wild fig-trees, which pierces that of the cultivated, in order to deposit its eggs within; at the same time diffusing within the receptacle the farina of the male flowers. Without this operation the fruit may ripen, but no effective seeds are produced: hence the garden fig can only be propagated by layers and cuttings, in those countries where the wild fig is not known. The process of thus ripening the fruit, in the oriental countries, is not left to nature, but is managed with great art, and different degrees of dexterity, so as to reward the skilful husbandman with a much larger increase of fruit than would otherwise be produced. A tree of the same size, which, in Provence, where caprification is not practised, may produce about 25 pounds of fruit, will, by that art, in the Grecian islands, bring ten times that quantity.

FIFE, (*Encycl.*) This county, anciently called *Ros*, including the shire of Kinross, is a peninsula lying between the Friths of Forth and Tay. It is bounded on the north by the Frith of Tay; on the south by the Frith of Forth, which divides it from the Lothians; on the west by the Ochil hills; and on the east by the German Ocean.

FINE DRAWING, in the manufactories. See **RENTERING**.

The term is particularly used for a rent or hole happening in the dressing or preparing of a piece of cloth, artfully sewed up or mended with silk.

All fine-drawings are reputed defects or blemishes, and ought to be allowed for in the price of the

the piece.—Hence, M. Savary establishes it as a rule, which is certainly founded on natural equity, that every manufacturer mark the fine drawings of his cloths with a piece of packthread tied to the list; to direct the draper to the spot; and that the draper apprise the taylor or other person to whom he sells it of the same, that he may not come to damage in the cutting; there being instances of drapers condemned to take back their cloth, when cut to pieces, for omitting to mention the fine-drawings and other flaws.

On this occasion M. Savary extols the procedure of an English merchant, who sending a piece of cloth damaged in one spot, to his correspondent at Paris, put a piece of gold in the damaged place, to make up the damage.—But as this example is perhaps the only one of its kind, that author recommends it to the merchant or draper to unfold all the pieces entirely as they come to him; to discover the fine-drawings and other flaws, in order to make the clothier accountable for them.

FINGAL, king of Morven, or ancient Caledonia. He flourished in the third century; and according to the Irish histories died in the year 283, although there is some reason from Ossian's poems for placing his death a few years later. Fingal was descended in all probability from those Celtic tribes who were the first inhabitants of Britain. Tradition, and the poems of Ossian, give him a long line of royal ancestors, such as Combal, Trenmor, Trathal, &c. who had all reigned over the same territory. Whether this territory was bounded by the Caledonian forest, or extended somewhat farther to the south, towards the Roman province, is uncertain; but there is no doubt of its having extended over all the north and west Highlands, comprehending the Hebrides, whose petty chiefs were all subject to the king of Morven. His principal place of residence was Selma, which was probably in the neighbourhood of Glenco, supposed to be the Cona of Ossian; though some imagine it to have been in Strath-Conan in Moray. The truth seems to be, that as Fingal and his people lived by hunting, they often shifted their habitation. Hence, in all parts of the Highlands we find, in the names of places, buildings, &c. such monuments as justify their several claims for the honour of Fingal's residence. Fingal acquired great fame by his prowess in arms. He made many successful incursions into the Roman province, from whence he carried away those spoils which his son so often mentions under the names of *the wine of the stranger*, and *the wax of the stranger*. By sea we find him frequently making voyages to Scandinavia, the Orkneys, and Ireland; called by Ossian *Lochlin*, *Innisfroe*, and *Ullin*. Several of these expeditions were celebrated by his son in epic poems, of which two only remain, Fingal and Temora. In the last of these poems, we find Fingal fighting together with his grandson Oskar. How long he lived afterwards is uncertain. He is said to have died a natural death; and therefore none of his son's poems relate to this event, though it is occasionally mentioned in many of them. "Did thy beauty last, O Ryno? Stood the strength of car-borne Oskar? Fingal himself passed away; and the halls of his fathers have forgot his steps. The blast of the north opens thy gates, O king, and I behold thee sitting on mist, dimly gleaming in all thine

arms. Thy form now is not the terror of the valiant; but like a watery cloud, when we see the stars behind it, with their weeping eyes. Thy shield is like the aged moon; thy sword vapour half kindled with fire. Dim and feeble is the chief who, travelled in brightness before.—But thy steps are on the winds of the desert, and the storms darken in thy hand. Thou takest the sun in thy wrath, and hidest him in thy clouds. The fons of little men are afraid, and a thousand showers descend."—*Barrathon*.

"The character of Fingal is perhaps the most perfect that was ever drawn by a poet, for we may boldly defy all the writers of antiquity to show us any hero equal to Fingal. Throughout the whole of Ossian's works, he is presented to us in all that variety of lights which give the full display of a character. In him concur almost all the qualities that can ennoble human nature; that can either make us admire the hero, or love the man. He is not only unconquerable in war, but he makes his people happy by his wisdom in the days of peace. He is truly the father of his people. He is known by the epithet of "Fingal of the mild look," and distinguished on every occasion by humanity and generosity. He is merciful to his foes, full of affection to his children, full of concern about his friends, and never mentions Agandecca, his first love, without the utmost tenderness. He is the universal protector of the distressed: none ever went sad from Fingal.—"O Oskar! bend the strong in arms, but spare the feeble hand. Be thou a stream of many tides against the foes of thy people; but like the gale that moves the grass to those who ask thine aid: so Trenmor lived; such Trathal was; and such has Fingal been. My arm was the support of the injured; the weak rested behind the lightning of my steel." These were the maxims of true heroism, to which he formed his grandson. His fame is represented as every where spread; the greatest heroes acknowledge his superiority; his enemies tremble at his name; and the highest encomiums that can be bestowed on one whom the poet would most exalt, is to say, That his soul was like the soul of Fingal. Wherever he appears, we behold the hero. The objects he pursues are always great; to bend the proud, to protect the injured, to defend his friends, to overcome his enemies by generosity more than by force.

"Some strokes of human imperfection and frailty are what usually give us the most clear view and the most sensible impression of a character, because they present to us a man such as we have seen; they reveal known features of human nature. When poets go beyond this range, and attempt to describe a faultless hero, they, for the most part, set before us a sort of vague undistinguishable character, such as the imagination cannot lay hold of, or realize to itself as the object of affection. But Fingal, though exhibited without any of the common human failings, is nevertheless a real man; a character which touches and interests every reader." *Dr Blair*.

We may observe, that Fingal appears to have been no less a poet than a warrior; at least in all those passages ascribed to him in the poems of his son, there is a grandeur and loftiness that elevates them above the common style even of Ossian. The following passage from the poem of *Carthon* may be taken as a speci-

Fire.

Fire.

men of Fingal's poetry.—“ Raife, ye bards,” said the mighty Fingal, “ the praise of unhappy Moina. Call her ghost, with your songs, to our hills; that she may rest with the fair of Morven, the sunbeams of other days, and the delight of heroes of old.—I have seen the walls of Balclutha, but they were desolate. The fire had rebounded in the halls: and the voice of the people is heard no more. The stream of Clutha was removed from its place by the fall of the walls. The thistle shook, there, its lonely head: the mofs whistled to the wind. The fox looked out from the windows; the rank gras of the wall waved round his head. Desolate is the dwelling of Moina: silence is in the house of her fathers. Raife the song of mourning, O bards, over the land of strangers. They have but fallen before us; for, one day we must fall.—Why dost thou build the hall, son of the winged days? Thou lookest from thy towers to-day; yet a few years, and the blast of the desert comes; it howls in thy empty court, and whistles round thy half-worn shield.—And let the blast of the desert come! We shall be renowned in our day. The mark of my arm shall be in the battle, and my name in the song of bards. Raife the song; send round the shield: and let joy be heard in my hall. When thou, son of heaven, shalt fail! if thou shalt fail, thou mighty light! if thy brightness is for a season, like Fingal; our fame shall survive thy beams.”

‘ Such was the joy of Fingal in the day of his joy. His thousand bards leaned forward from their seats, to hear the voice of the king. It was like the music of the harp on the gale of the spring. Lovedly were thy thoughts, O Fingal! Why had not Ossian the strength of thy soul? But thou standest alone, my father; and who can equal the king of Morven?’

FIRE, Method of securing BUILDINGS against it.—Dr Hales proposes to check the progress of fires by covering the floors of the adjoining houses with earth. The proposal is founded on an experiment which he made with a fir-board half an inch thick, part of which he covered with an inch depth of damp garden mould, and then lighted a fire on the surface of the mould: though the fire was kept up by blowing, it was two hours before the board was burnt through, and the earth prevented it from flaming. The thicker the earth is laid on the floors, the better: however, Dr Hales apprehends that the depth of an inch will generally be sufficient; and he recommends to lay a deeper covering on the stairs, because the fire commonly ascends by them with the greatest velocity.

Mr Hartley made several trials in the years 1775 and 1776, in order to evince the efficacy of a method which he had invented for restraining the spread of fire in buildings. For this purpose thin iron plates are well nailed to the tops of the joists, &c. the edges of the sides and ends being lapped over, folded together, and hammered close. Partitions, stairs, and floors, may be defended in the same manner; and plates applied to one side have been found sufficient. The plates are so thin as not to prevent the floor from being nailed in the joists, in the same manner as if this preventative were not used; they are kept from rust by being painted or varnished with oil and turpentine. The expense, of this addition, when extended through a whole building, is estimated at about 5 per cent. Mr

Hartley has a patent for this invention, and parliament has voted a sum of money towards defraying the expense of his numerous experiments. The same preventative may also be applied to ships, furniture, &c.

Lord Mahon has also discovered and published a very simple and effectual method of securing every kind of building against all danger of fire. This method he has divided into three parts, viz. under-flooring, extra-lathing, and inter-securing.

The method of underflooring is either single or double: In single underflooring, a common strong lath of oak or fir, about one-fourth of an inch thick, should be nailed against each side of every joist, and of every main timber, supporting the floor which is to be secured. Other similar laths are then to be nailed along the whole length of the joists, with their ends butting against each other. The top of each of these laths or fillets ought to be at 1½ inch below the top of the joists or timbers against which they are nailed; and they will thus form a sort of small ledge on each side of all the joists. These fillets are to be well bedded in a rough plaster hereafter mentioned, when they are nailed on, so that there may be no interval between them and the joists; and the same plaster ought to be spread with a trowel upon the tops of all the fillets, and along the sides of that part of the joists which is between the top of the fillets and the upper edge of the joists. In order to fill up the intervals between the joists that support the floor, short pieces of common laths, whose length is equal to the width of these intervals, should be laid in the contrary direction to the joists, and close together in a row, so as to touch one another: their ends must rest upon the fillets, and they ought to be well bedded in the rough plaster, but are not to be fastened with nails. They must then be covered with one thick coat of the rough plaster, which is to be spread over them to the level of the tops of the joists: and in a day or two this plaster should be trowelled over close to the sides of the joists, without covering the tops of the joists with it.

In the method of double-flooring, the fillets and short pieces of laths are applied in the manner already described; but the coat of rough plaster ought to be little more than half as thick as that in the former method. Whilst this rough plaster is laid on, some more of the short pieces of laths above-mentioned must be laid in the intervals between the joists upon the first coat, and be dipped deep in it. They should be laid as close as possible to each other, and in the same direction with the first layer of short laths. Over this second layer of short laths there must be spread another coat of rough plaster, which should be trowelled level with the tops of the joists without rising above them. The rough plaster may be made of coarse lime and hair; or instead of hair, hay chopped to about three inches in length may be substituted with advantage. One measure of common rough sand, two measures of slacked lime, and three measures of chopped hay, will form in general a very good proportion, when sufficiently beat up together in the manner of common mortar. The hay should be put in after the two other ingredients are well beat up together with water. This plaster should be made stiff; and when the flooring boards are required to be laid down very soon, a fourth or fifth part of quicklime in powder, formed by

by dropping a small quantity of water on the limeſtone a little while before it is uſed, and well mixed with this rough plaſter, will cauſe it to dry very faſt. If any cracks appear in the rough plaſter-work near the joists when it is thoroughly dry, they ought to be cloſed by waſhing them over with a buſh wet with mortar-waſh: this waſh may be prepared by putting two meaſures of quicklime, and one of common ſand, in a pail, and ſtirring the mixture with water till the water becomes of the conſiſtence of a thin jelly.

Before the flooring boards are laid, a ſmall quantity of very dry common ſand ſhould be ſtrewed over the plaſter-work, and ſtruck ſmooth with an hollow rule, moved in the direction of the joists, ſo that it may lie rounding between each pair of joists. The plaſter-work and ſand ſhould be perfectly dry before the boards are laid, for fear of the dry rot. The method of under-flooring may be ſucceſsfully applied to a wooden ſtair-caſe; but no ſand is to be laid upon the rough plaſter-work. The method of extra-lathing may be applied to cieling joists, to ſloping roofs, and to wooden partitions.

The third method, which is that of inter-ſecuring, is very ſimilar to that of under-flooring; but no ſand is afterwards to be laid upon it. Inter-ſecuring is applicable to the ſame parts of a building as the method of extra-lathing, but it is ſeldom neceſſary.

Lord Mahon has made ſeveral experiments in order to demonſtrate the efficacy of theſe methods. In moſt houſes it is only neceſſary to ſecure the floors; and the extra-expence of under-flooring, including all materials, is only about nine pence per ſquare yard, and with the uſe of quicklime a little more. The extra-expence of extra-lathing is no more than ſix pence per ſquare yard for the timber ſide-walls and partitions; but for the cieling about nine pence per ſquare yard. But in moſt houſes no extra-lathing is neceſſary.

FIRE-EATER. We have a great number of mountebanks who have procured the attention and wonder of the public by eating of fire, walking on fire, waſhing their hands in melted lead, and the like tricks.

The moſt celebrated of theſe was our countryman Richardſon, much talked of abroad. His ſecret, as related in the *Journal des Sçavans*, of the year 1680, conſiſted in a pure ſpirit of ſulphur, wherewith he rubbed his hands, and the parts that were to touch the fire; which burning and cauterizing the epidermis, hardened and enabled the ſkin to reſiſt the fire.

Indeed, this is no new thing: Amb. Paré aſſures us he had tried it on himſelf, that after waſhing the hands in urine, and with unguentum aurcum, one may ſafely waſh them in melted lead.

He adds alſo, that by waſhing his hands in the juice of onions he could bear a hot ſhovel on them while it melted lead.

FLATUS. For INDEX ſubjoined to *Medicine*, read *MEDICINE*, n° 384.

FLAX-PLANT. (*Phormium tenax*, Forſt.) is a name which we may give to a plant that ſerves the inhabitants of New Zealand inſtead of hemp and flax. Of this plant there are two ſorts; the leaves of both reſemble thoſe of flax, but the flowers are ſmaller, and their cluſters more numerous; in one kind they are yellow, and in the other a deep red. Of the leaves of theſe plants, with very little preparation, they make

all their common apparel, and alſo their ſhirts, lines, and cordage, for every purpoſe; which are ſo much ſtronger than any thing we can make with hemp, that they will not bear a compariſon. From the ſame plant, by another preparation, they draw long ſlender fibres, which ſhine like ſilk, and are as white as ſnow: of theſe, which are very ſtrong, they make their fineſt cloaths; and of the leaves, without any other preparation than ſplitting them into proper breadths, and tying the ſtrips together, they make their fiſhing-nets, ſome of which are of an enormous ſize.

The ſeeds of this valuable plant have been brought over into England; but, upon trial, appeared to have loſt their vegetating power.

The filamentous parts of different vegetables have been employed in different countries for the ſame mechanic uſes as hemp and flax among us. Putrefaction, and in ſome degree alkaline lixivium, deſtroy the pulpy or fleſhy matter, and leave the tough filaments entire. By curiouſly putrefying the leaf of a plant in water, we obtain the fine flexible fibres, which conſtituted the baſis of the ribs and minute veins, and which form as it were a ſkeleton of the leaf. In Madagaſcar, different kinds of cloth are prepared from the filaments of the bark of certain trees boiled in ſtrong ley; and ſome of theſe cloths are very fine, and approach to the ſoftneſs of ſilk, but in durability come ſhort of cotton: others are coarſer and ſtronger, and laſt thrice as long as cotton; and of theſe filaments they make ſails and cordage for their veſſels. The ſtalks of nettles are ſometimes uſed for like purpoſes, even in France; and Sir Hans Sloane relates, in one of his letters to Mr Ray, that he has been informed by ſeveral, that muſlin and callico, and moſt of the Indian linens, are made of nettles. A ſtrong kind of cloth is ſaid to be prepared, in ſome of the provinces of Sweden, of hop-ſtalks; and in the Tranſactions of the Swediſh Academy for 1750, we have an account of an experiment relating to this ſubject: A quantity of the ſtalks was gathered in autumn, which was equal in bulk to a quantity of flax ſufficient to yield a pound after preparation. The ſtalks were put into water, and kept covered with it during the winter. In March they were taken out, dried in a ſtove, and dreſſed as flax. The prepared filaments weighed nearly a pound, and proved fine, ſoft, and white; they were ſpun and wove into fix ells of fine ſtrong cloth. Unleſs the ſtalks are fully rotted, which will take much longer time than flax, the woody part will not ſeparate, and the cloth will prove neither white nor fine.

FLETCHER (Andrew) of Salton, a celebrated Scots patriot and political writer, was deſcended from an ancient family who trace their origin to one of the followers of William the Conqueror. He was the ſon of Sir Robert Fletcher of Salton and Innerpeffer, and born in the year 1650. The tuition of our author was committed by his father, on his deathbed, to Mr (afterwards Biſhop) Burnet, then his pariſh-miſter; by whole care he received a pious, learned, and polite education. Endowed with uncommon genius, and poſſeſſed of virtues and abilities peculiarly ſuited to the times in which he lived, Mr Fletcher quickly ſhone forth the ornament of his country, and the champion of its freedom. Having in the courſe of his clafſical ſtudies

Flax;
Fletcher.

Fletcher.

Studies and historical reading been impressed with an enthusiastic admiration both of ancient and modern republics, he had early contracted an ardent love of liberty, and an aversion to arbitrary rule. Hence his spirit the more readily took alarm at certain measures in the reign of Charles the Second. Being knight of the shire for Lothian to that parliament where the duke of York was commissioner, he openly opposed the designs of that prince, and the bill of accession. He had a share with lord viscount Stair in framing the test-act, by which the duke of York complained that he lost Scotland. On these accounts, he became peculiarly obnoxious to the duke; and was at last obliged to flee to Holland, to avoid the fatal consequences of prosecutions which on various pretences were commenced against him: being cited before the privy-council and judicatory courts, and not appearing, he was declared traitor, and his estate confiscated.

In Holland he and Mr Baillie of Jerviswood were the only persons whom the earl of Argyle consulted concerning the designs which were then in agitation. In 1681 they came over to England, in order to concert matters with their party in that country; and were the only two who were intrusted so far as to be admitted to the secrets of lord Russell's council of six. Mr Fletcher managed his part of the negotiation with so much address, that administration could find no pretext for seizing him: nor could they fix upon him those articles on account of which Mr Baillie was condemned; to whose honour let it be remembered, that although offered a pardon on condition of his accusing his friend, he persisted in rejecting the proposal with indignation.

Mr Fletcher having joined the duke of Monmouth upon his landing, received a principal command under him. But the duke was deprived of his services on the following occasion, as related by Sir John Dalrymple. Being sent upon an expedition, and not esteeming "times of danger to be times of ceremony, he had seized for his own riding the horse of a country gentleman [the mayor of Lynne] which stood ready equipt for its master. The master, hearing this, ran in a passion to Fletcher, gave him opprobrious language, shook his cane, and attempted to strike. Fletcher, though rigid in the duties of morality, yet having been accustomed to foreign services both by sea and land, in which he had acquired high ideas of the honour of a soldier and a gentleman, and of the affront of a cane, pulled out his pistol, and shot him dead on the spot. The action was unpopular in countries where such refinements were not understood. A clamour was raised against it among the people of the country: in a body, they waited upon the duke with their complaints; and he was forced to desire the only soldier, and almost the only man of parts, in his army, to abandon him. With Fletcher all Monmouth's chances of success in war left him." But, in a manuscript memoir belonging to the family, we have the following notice concerning Mr Fletcher's connection with Monmouth, in which his separation from that prince is very differently accounted for: "To lord Marischal Mr Fletcher explained the motives which induced him first to join, and afterwards abandon, the duke of Monmouth. The former he ascribed to the duke's manifesto in Scotland relating to religion, and in England

to liberty. For the latter he accounted by the disgust produced in his own mind and that of his associates, when the duke declared himself king, and broke faith with all who embarked with him on his principles. He complained heavily of the account commonly given of the death of the mayor of Lynne; and mentioned to Lord Marischal, in proof of the contrary, that he did not leave the duke till he came to Taunton, where he was proclaimed king, several weeks after the death of the mayor of Lynne."

Seeing all the efforts of himself and his friends in favour of liberty frustrated at Taunton, he endeavoured to secure his own personal freedom by taking his passage in the first ship bound to a foreign country. It was his misfortune to land in Spain; where he was immediately arrested, cast into prison, and guarded by three different bands of soldiers, till a vessel should be prepared to carry him a victim in chains to the court of London. But on the morning before the ship could fail, whilst he looked pensive through the bars that secured the window of his room, he was hailed by a venerable personage who made signs to speak with him. The prison-doors he found open, and whilst his friendly conductor waved to him to follow him, he passed thro' three different guards of soldiers all fast asleep. Without being permitted to offer his thanks to his deliverer, he found himself obliged to prosecute with all speed the journey, in which he was directed by a person concerning whom he could never collect any information; and in disguise he proceeded in safety through Spain. He felt a peculiar pleasure in relating to his friends instances of the care of Providence which he had experienced during his exile; and entertained them often with narratives of this kind, which he always mingled with religious reflections. Of these, another may be here mentioned. Happening in the evening to pass the skirt of a wood at a few miles distance from a city where he intended to lodge, he came to a place where two roads met. After he had entered upon the road on the right, he was accosted by a female of a respectable figure, who warned him to turn back, and take the road on the left; for that in the other there was danger which he could not escape if he continued to proceed. After which she suddenly retired into the wood, out of which she had issued no less unexpectedly. Having arrived at the city, the inhabitants were soon after alarmed by an account of the robbery and murder of several travellers who that evening had fallen into the hands of a banditti upon the very way in which he had intended to travel. From these and other instances of preservation from dangers, the devotion of his mind, habituated from his infancy to an intercourse with heaven, led him to conclude that he was in a peculiar manner the care of Providence; and that in critical cases his undershuffling received its direction from a supernatural impulse.

During his exile, he maintained a frequent and extensive correspondence with the friends of liberty at home; and he partly employed himself in making a curious collection of books, which compose the best private library in Scotland. But his genius also prompted him to engage in more active employments. He repaired to Hungary, and served several campaigns as a volunteer under the duke of Lorrain with great reputation. At length, understanding that the great

design then projecting in Holland, and upon the issue of which he considered the liberties of Britain to be suspended, had attained a considerable degree of maturity, he hastened thither; where his counsels and address were of eminent service. He came over with king William; and in zeal, activity, penetration, and political skill, proved inferior to none of the leaders in the Revolution.

Such, however, was his magnanimity, that from a survey of K. William's papers it appears, that while others laboured to turn this grand event to the emolument of themselves and the aggrandisement of their family, Mr Fletcher asked nothing. His estate had been forfeited, and his house abandoned to military discretion; his fortune was greatly shattered, and his family reduced to circumstances of distress. Nothing was given him in recompence of all his sufferings. On the contrary, he, together with the duke of Hamilton, was distinguished by marks of royal and ministerial dislike. Still, whatever private resentment he might entertain, it appeared that his ruling principle was the good of his country; and that to this grand object of his heart he was willing to sacrifice all private resentments. For when, in 1692, the abdicated king meditated an invasion, Mr Fletcher addressed a letter (preserved in Sir John Dalrymple's Collection) to the duke of Hamilton, in which every argument is employed with skill and energy to engage his Grace to forget his injuries, and in the present crisis to employ the extensive influence and authority he then possessed in the cause of freedom and of his country. This letter produced its full effect; and the duke returned to his duty, from which he had in part declined.

To follow our author through all the mazes of his political life subsequent to the Revolution, is beyond our purpose, and would exceed our limits. One or two circumstances more fall therefore suffice. Being elected a member for the parliament 1683, he showed an uniform zeal for the interest of his country. The thought of England's domineering over Scotland was what his generous soul could not endure. The indignities and oppression which Scotland lay under galled him to the heart; so that in his learned and elaborate discourses, he exposed them with undaunted courage and pathetic eloquence.—In that great event, the Union, he performed essential service. He got the act of security passed, which declared that the two crowns should not pass to the same head till Scotland was secured in her liberties civil and religious. Therefore lord Godolphin was forced into the Union, to avoid a civil war after the queen's demise. Although Mr Fletcher disapproved of some of the articles, and indeed of the whole frame of the Union; as the act of security was his own work, he had all the merit of that important transaction.

We must not omit mentioning, that in the ardour of his political career Mr Fletcher forgot not the interests of the place that gave him birth. He esteemed the education of youth one of the noblest objects of government. On this subject he wrote a treatise, still extant, most characteristic of himself; and he established at Salton a foundation for the same purpose, of great utility while it lasted.

This great man died at London in 1716, aged 66.

His remains were conveyed to Scotland, and deposited in the family vault at Salton.

That Mr Fletcher received neither honours nor emoluments from king William, may perhaps be in part attributed to himself; a circumstance, however, which must add greatly to the lustre of his character. His uncomplaining virtue, and the sternness of his principles, were ill calculated to conciliate courtly favour. He was so zealous an assertor of the liberties of the people, that he was too jealous of the growing power of all princes; in whom he thought ambition so natural, that he was not for trusting the best of kings with the power which ill ones might make use of against their subjects: he was of opinion that all princes were made by, and for the benefit of, the people; and that they should have no power but that of doing good. This, which made him oppose king Charles and invade king James, led him also to oppose the giving so much power to king William, whom he would never serve after his establishment. So we are told by the author of *Short political Characters*, a MS. in the library of the late T. Rawlinson, Esq.—Mr Lockhart, in his *Memoirs*, p. 72. expresses a belief that his aversion to the English and to the Union was so great, that, in revenge to them, he was inclined to side with the abdicated family: "But (adds he) as that was a subject not fit to be entered upon with him, this is only a conjecture from some innuendos I have heard him make: but so far is certain, he liked, commended, and covered with high-flying Tories, more than any other set of men; acknowledging them to be the best countrymen, and of most honour, integrity, and ingenuity." It seems difficult to reconcile this with Mr Fletcher's avowed principles and the general tenor of his conduct. May we suppose, that chagrin, if not at the neglect or the ill treatment which he had himself received from government since the Revolution, yet at the public measures relating to his native country, might have occasioned him to relent in his sentiments with regard to the exiled family?—In the family-memoirs already quoted, we are informed, that "Lord Marischal held Mr Fletcher's character in high admiration;" and that, "when governor of Neuchâtel, where Rousseau resided about the year 1766, he prevailed with this very extraordinary genius to write the life of a man whose character and actions he wished to have transmitted to posterity with advantage. For this purpose, his lordship applied to an honourable relation of Mr Fletcher's for materials, which by him were transmitted to lord Marischal: but the design failed through Rousseau's desultory and capricious disposition." This anecdote must appear incompatible with the known loyalty and attachments of the Earl Marischal, unless we suppose him to have been privy to some such sentiments of Mr Fletcher, as those alluded to by Mr Lockhart: for how could we suppose him anxious to promote a composition, in which the task would be to celebrate principles diametrically opposite to his own, and to applaud actions subversive of that royal family in whose cause he had ventured his life, and forfeited his fortune, and forgone his country!—But however these circumstances may be reconciled,—as the integrity, disinterestedness, and public spirit of Mr Fletcher, have been universally acknowledged, there is reason to believe, that all his sentiments and actions

were

Fletcher
||
Fossils.

were founded in honour, and that he never once pursued a measure further than he judged it to be for the interest of his country.

Mr Fletcher was master of the English, Latin, Greek, French, and Italian languages; and well versed in history, the civil law, and all kinds of learning. In his travels, he had not only acquired considerable knowledge in the art of war, but also became versant in the respective interests of the several princes and states of Europe. In private life, he was affable to his friends, and free from all manner of vice. He had a penetrating, clear, and lively apprehension; but is said to have been too much wedded to opinions, and impatient of contradiction.—He possessed an uncommon elevation of mind, accompanied with a warmth of temper, which would suffer him to brook from no rank among men, nor in any place, an indignity. Of this he exhibited a singular proof in the Scots parliament. The Earl of Stair, secretary of state and minister for Scotland, having in the heat of debate used an improper expression against Mr Fletcher, he seized him by his robe, and insisted upon public and immediate satisfaction. His Lordship was obliged instantly to beg his pardon in presence of parliament.

Mr Fletcher was by far the finest speaker in the parliament of Scotland: the earl of Stair alone rivalled him. The latter was famed for a splendid, the former for a close and nervous eloquence. He formed his style on the models of antiquity; and the small volume of his works, Sir John Dalrymple observes, tho' imperfectly collected, is one of the very few classical compositions in the English language.

FLOS MASCULUS, in botany, a flower which contains the stamen, reckoned by the sexualists the male organ of generation; but not the stigma or female organ. All the plants of the class diœcia of Linæus have male and female flowers upon different roots: those of the class monœcia bear flowers of different sexes on the same root. The plants, therefore, of the former are only male and female: those of the latter are androgynous; that is, contain a mixture of both male and female flowers.

FOSSILS, (*Encycl.*) The adventitious or extraneous fossils, or those which include the subterraneous exuvie of different sea and land animals, and even vegetables, as shells, teeth, leaves, stalks, &c. which are found buried in great abundance in divers parts of the earth, have employed the curiosity of several of our latest naturalists, who have each their several system to account for the surprising appearances of petrified sea-fishes, in places far more remote from the sea, and on the tops of mountains; shells in the middle of quarries of stone; and of elephants teeth, and bones of divers animals, peculiar to the southern climates, and plants only growing in the east, found fossil in our northern and western parts. See Plate CCCXVII.

Some will have these shells, &c. to be real stones, and stone plants, formed after the usual manner of other figured stones; of which opinion is our learned Dr Lister.

Another opinion is, that these fossil shells, with all other foreign bodies found within the earth, as bones, trees, plants, &c. were buried therein at the time of the universal deluge; and that, having been

penetrated either by the bituminous matter abounding chiefly in watery places, or by the salts of the earth, they have been preserved entire, and sometimes petrified.

Others think, that those shells, found at the tops of the highest mountains, could never have been carried thither by the waters, even of the deluge; inasmuch as most of these aquatic animals, on account of the weight of their shells, always remain at the bottom of the water, and never move but close along the ground.

They imagine, that a year's continuance of the waters of the deluge, intermixed with the salt waters of the sea, upon the surface of the earth, might well give occasion to the production of shells of diverse kinds in different climates; and that the universal saltness of the water was the real cause of their resemblance to the sea-shells, as the lakes formed daily by the retention of rain or spring water produce different kinds.

Others think, that the waters of the sea, and the rivers, with those which fell from heaven, turned the whole surface of the earth upside down; after the same manner as the waters of the Loire, and other rivers, which roll in a sandy bottom, overturn all their sands, and even the earth itself, in their swellings and inundations; and that in this general subversion, the shells came to be interred here, fishes there, trees there, &c.

But nobody has set this system in a better light than Dr Woodward, in his Natural History of the Earth. That author, pursuing and improving the hypothesis of Dr Burnet, maintains the whole mass of earth, with every thing belonging thereto, to have been so broken and dissolved at the time of the deluge, that a new earth was then formed in the bosom of the water, consisting of different strata, or beds of terrestrial matter, ranged over each other usually according to the order of their specific gravities. By this means, plants, animals, and especially fishes and shells, not yet dissolved among the rest, remained mixed and blended among the mineral and fossil matters; which preserved them, or at least assumed and retained their figures and impressions either indentedly, or in relieve.

FOTHERGILL (Dr John), a late eminent physician, was born in 1712, at Wensley-dale in Yorkshire. His father had been bred to the profession of husbandry, and occupied a small estate of his own in that country. The Doctor was the second of five children (four sons and a daughter), and received his education in the seminary belonging to the Quakers; and afterwards served his time to one Mr Bartlett an apothecary at Bradford. From thence he removed to London, and became a pupil of Dr (afterwards Sir Edward) Wilmot, at St Thomas's Hospital. He then went to the university of Edinburgh, where he took his degree in 1736. From Edinburgh he went to Leyden; whence, after a short stay, he returned to London, and began to practise physic about the year 1740, in a house in White-hart Court, Lombard-street, where he resided during the greatest part of his life, and acquired most of his fortune. In 1744 he was admitted a licentiate of the college of physicians in London; and in 1754 a fellow of that of Edinburgh, to which he was a considerable benefactor. He afterwards became a member of the Royal Medical Society at Paris,

Fossil,
Fothergill.

ria, and a member both of the Royal and Antiquarian Societies. He continued his practice with unremitting attention and success, till his illness, during the two last years of his life, obliged him to give up a considerable part of it. The disorder which hastened his death, was a scirrhus of the prostate gland, and an obstruction in the bladder, in which were found two quarts of water after his decease. This had been gradually coming upon him for six years, by reason of his delicacy, which made him unwilling to alight often from his carriage; and when, after his temporary recovery from it the year before he died, he submitted to use relief in his carriage, it was too late. He died in his house in Harpur-street, Dec. 26. 1780.

Dr Fothergill, besides his attention to medicine, had imbibed an early taste for natural history, which was improved by his friend Mr Collinson. He was for many years a valuable contributor to the Gentleman's Magazine; which, in return, considerably assisted his rising fame. His observations on the Weather and Diseases were begun in 1751, and continued monthly for many years. He did not add to the medical art any great or valuable improvements. His pamphlet on the Ulcerous Sore Throat is in every respect the best of his performances, and owes much of its merit to the information of the late Drs Leatherland and Sylvester. It was first printed in 1748, on the re-appearance of that fatal disorder, which, in 1739, had carried off the two sons of Mr Pelham. At the expense of Dr Fothergill also was made and published a new translation of the whole Bible, by Anthony Porver a Quaker, who, by his own industry, acquired a knowledge of the Hebrew, Greek, and Latin languages. This publication is said to have cost the Doctor not less than 2000*l*. It appeared in 1764 in two vols folio; and in 1780 was published an edition of Dean Percy's Key to the New Testament, adapted to the use of a seminary of young Quakers at Ackworth, near Leeds in Yorkshire. This was founded in 1778 by the society, who purchased by subscription, in which Dr Fothergill's name stood foremost, the house and estate of 30 acres possessed by the Foundling Hospital, but which they found inconvenient for their purpose on account of distance. The Doctor first projected this on the plan of a smaller institution of the same kind at Gilderfomes. He also endowed it handsomely by his will. It now contains about 300 children of both sexes, who are fed and instructed.

The fortune acquired by Dr Fothergill was immense; and, taking all things together, the computation cannot be less than 80,000*l*. His business, when in full practice, was valued at 7000*l*. a-year. In the influenza of 1775 and 1776, he is said to have had 60 patients daily on his list, and his profit was estimated at 8000*l*.—When the infirmities of old age obliged him to relax his close attention to business, he quitted his house in the city, and resided in Harpur-street, Red-lion Square. He also furnished himself with a pleasant retreat at Upton, which he used to visit on Saturdays during the winter, and sometimes more frequently in spring and summer. For several years before his death he was accustomed to retire in the month of July to Lea-Hall, a pleasant estate in the neighbourhood of Middlewich, which he rented from Sir John Leicester. He generally resided

at this place till the latter end of September; and while here took no fees, but used to go once a-week to an inn at Middlewich, and prescribe gratis to all who applied to him.

Dr Fothergill's character was excellent. A transaction, indeed, with regard to one Dr Leeds gave occasion to some of his enemies to blame him; but how unjustly, has been abundantly shown by his biographers Dr Elliot and Dr Lettome.

Dr Fothergill wrote a considerable number of Tracts, which are now collected into one vol. 8vo, by Dr Elliott. He sometimes wrote in the newspapers, and is said to have been the author of more than 100 letters in the Gazetteer concerning the New Pavement.

FRAXINELLA, in botany. See DICTAMNUS, (*Encycl.*)—It is remarkable of this odorous plant, that, when in full blossom, the air which surrounds it in a still night, may be inflamed by the approach of a lighted candle. Dr Watson doubts whether this inflammability proceeds from an inflammable air which is exhaled by the plant, or from some of the finer parts of the essential oil of the plant being dissolved in the common atmospheric air. The latter is the most probable supposition; for were it the pure inflammable air, as Mr Cavallo observes, it would, on account of its small specific gravity, leave the plant as soon as it was produced. Common air acquires the property of becoming inflammable, by being transmitted through several essential oils.

FRENUM, in anatomy, the same with the *ligamentum annulare*, or annular ligament.—This name is given to a ligament on each ankle and each wrist, and this more on account of their use than their figure. They bridle the tendons of the muscles which pass through them.

FROST, (*Encycl.*) The great power of frost on vegetables is a thing sufficiently known; but the differences between the frosts of a severe winter, and those which happen in the spring mornings, in their effects on plants and trees, were never perfectly explained, till by M. Du Hamel and Buffon in the Memoirs of the Paris Academy.

The frosts of severe winters are much more terrible than those of the spring, as they bring on a privation of all the products of the tenderer part of the vegetable world; but then they are not frequent, such winters happening perhaps but once in an age; and the frosts of the spring are in reality greater injuries to us than these, as they are every year repeated.

In regard to trees, the great difference is this, that the frosts of severe winters affect even their wood, their trunks and large branches; whereas those of the spring have only power to hurt the buds.

The winter frosts happening at a time when most of the trees in our woods and gardens have neither leaves, flowers, nor fruits upon them, and have their buds so hard as to be proof against slight injuries of weather, especially if the preceding summer has not been too wet; in this state, if there are no unlucky circumstances attending, the generality of trees bear moderate winters very well; but hard frosts, which happen late in the winter, cause very great injuries even to those trees which they do not utterly destroy. These are, 1. Long cracks following the direction of the fibres. 2. Parcels of dead wood inclosed round

Frost.

with wood yet in a living state. And, 3. That diftemperature which the foresters call the *double blea*, which is a perfect circle of blea, or soft white wood, which, when the tree is afterwards felled, is found covered by a circle of hard and solid wood.

The opinions of authors about the expositions of trees to the different quarters, have been very different, and most of them grounded on no rational foundation. Many are of opinion that the effects of frost are most violently felt on those trees which are exposed to the north; and others think the south or the west the most strongly affected by them. There is no doubt but the north exposure is subject to the greatest cold. It does not, however, follow from this, that the injury must be always greatest on the trees exposed to the north in frosts: on the contrary, there are abundant proofs that it is on the south side that trees are generally more injured by frost: and it is plain from repeated experiments, that there are particular accidents, under which a more moderate frost may do more injury to vegetables, than the most severe one which happens to them under more favourable circumstances.

It is plain from the accounts of the injuries trees received by the frosts in 1709, that the greatest of all were owing to repeated felle thaws, succeeded by repeated new frosts. But the frosts of the spring-season furnish abundantly more numerous examples of this truth; and some experiments made by the Count de Buffon, at large in his own woods, prove incontestably, that it is not the severest cold, or most fixed frost, that does the greatest injury to vegetables.

This is an observation directly opposite to the common opinion; yet is not the less true, nor is it any way discordant to reason. We find by a number of experiments, that humidity is the thing that makes frost fatal to vegetables; and therefore every thing that can occasion humidity in them, exposes them to these injuries, and every thing that can prevent or take off an over proportion of humidity in them, every thing that can dry them, though with ever so increased a cold, must prevent or preserve them from those injuries. Numerous experiments and observations tend to prove this. It is well known that vegetables always feel the frost very desperately in low places where there are fogs. The plants which stand by a river side are frequently found destroyed by the spring and autumnal frosts, while those of the same species, which stand in a drier place, suffer little, or perhaps not at all by them; and the low and wet parts of forests are well known to produce worse wood than the high and drier. The coppice wood in wet and low parts of common woods, though it push out more vigorously at first than that of other places, yet never comes to so good a growth; for the frost of the spring killing these early top-shoots, obliges the lower part of the trees to throw out lateral branches: and the same thing happens in a greater or lesser degree to the coppice wood that grows under cover of larger trees in great forests; for here the vapours not being carried off either by the sun or wind, stagnate and freeze, and in the same manner destroy the young shoots, as the fogs of marshy places. It is a general observation also, that the frost is never hurtful to the late shoots of the vine, or to the flower-buds of trees, except when it

follows heavy dews, or a long rainy season, and then it never fails to do great mischief, tho' it be ever so slight.

The frost is always observed to be more mischievous in its consequences on newly cultivated ground than in other places; and this is because the vapours which continually arise from the earth, find an easier passage from those places than from others. Trees also which have been newly cut, suffer more than others by the spring frosts, which is owing to their shooting out more vigorously.

Frosts also do more damage on light and sandy grounds, than on the tougher and firmer soils, supposing both equally dry; and this seems partly owing to their being more early in their productions, and partly to their lax texture suffering a greater quantity of vapours to transpire.

It also has been frequently observed, that the side-shoots of trees are more subject to perish by the spring frosts than those from the top; and M. Buffon, who examined into this with great accuracy, always found the effects of the spring frosts much greater near the ground than elsewhere. The shoots within a foot of the ground quickly perished by them; those which stood at two or three feet high, bore them much better; and those at four feet and upwards frequently remained wholly unhurt, while the lower ones were entirely destroyed.

There are a series of observations, which have proved beyond all doubt, that it is not the hard frosts which so much hurt plants, as those frosts, tho' less severe, which happen when they are full of moisture; and this clearly explains the account of all the great damages done by the severe frosts being on the south side of the trees which are affected by them, tho' that side has been plainly all the while less cold than the north. Great damage is also done to the western sides of trees and plantations, when after a rain with a west wind the wind turns about to the north at sun-set, as is frequently the case in spring, or when an east wind blows upon a thick fog before sun-rising.

FUCUS, in botany, a genus of the order of algae, belonging to the cryptogamia class of plants. The most remarkable species are,

1. The ferratus, ferrated fucus, or sea-wrack. This is frequent at all seasons of the year upon the rocks at low-water mark, but produces its seeds in July and August. It consists of a flat, radical, and dichotomous leaf, about two feet long; the branches half an inch wide, ferrated on the edges with dents of unequal size, and at unequal distances, having a flat-stalk or rib divided like the leaf, and running in the middle of it through all its various ramifications. A small species of coralline, called by Linnæus *Sertularia pumila*, frequently creeps along the leaf. All the species of fucus afford a quantity of impure alkaline salt; but this much less than some others, eight ounces of the ashes yielding only three of fixed salt. The Dutch cover their crabs and lobsters with this fucus to keep them alive and moist; and prefer it to any other, as being destitute of those mucous vessels with which some of the rest abound, and which would sooner ferment and become putrid.

2. The vesiculosus, bladder fucus, common sea-wrack, or sea-ware. It grows in great abundance on the sea-rocks about low-water mark; producing its fructifications in July and August. It has the same habit, colour, and substance

Frost, Fucus.

stance as the foregoing; but differs from it in the following respects: The edges of the leaf have no serratures, but are quite entire. In the disc or surface are immersed hollow, spherical, or oval air-bladders, hairy within, growing generally in pairs, but often single in the angles of the branches, which are most probably air-bladders, destined to buoy up the plant in the water. Lastly, on the summits or extreme segments of the leaves, appear tumid vesicles about three quarters of an inch long, sometimes oval and in pairs, sometimes single and bifid, with a clear viscid mucus interspersed with downy hairs.—This species is an excellent manure for land; for which purpose it is often applied in the maritime parts of Scotland and other countries. In the islands of Jura and Skye it frequently serves as a winter-food for cattle, which regularly come down to the shores at the recess of the tides to seek for it. And sometimes even the flags have been observed, after a storm, to descend from the mountains to the sea-shores to feed upon this plant.

Linnaeus informs us, that the inhabitants of Gothland in Sweden boil this fucus in water, and mixing therewith a little coarse meal or flour feed their hogs with it; for which reason they call the plant *svintang*. And in Scania, he says, the poor people cover their cottages with it, and sometimes use it for fuel.

In Jura, and some other of the Hebrides, the inhabitants dry their cheeses without salt, by covering them with the ashes of this plant; which abounds with such quantity of salts, that from five ounces of the ashes may be procured two ounces and a half of fixed alkaline salts, that is, half of their whole weight.

But the most beneficial use to which the fucus vesiculosus is applied, in the way of economy, is in making pot-ash or kelp, a work much practised in the western isles.

There is great difference in the goodness and price of this commodity, and much care and skill required in properly making it. That is esteemed the best which is hardest, finest grained, and free from sand or earth. The price of kelp in Jura is 3*l.* 10*s.* per ton, and about 40 or 50 tons are exported annually from that island. So great a value is set upon this fucus by the inhabitants of that place, that they have sometimes thought it worth their while to roll fragments of rocks and huge stones into the sea, in order to invite the growth of it.

Its virtues in the medical way have been much celebrated by Dr Ruffel, in his Dissertation concerning the use of Sea-water in the Diseases of the Glands. He found the saponaceous liquor or mucus in the vesicles of this plant to be an excellent resolvent, extremely serviceable in dispersing all scorbutic and serophulous swellings of the glands. He recommends the patient to rub the tumour with these vesicles bruised in his hand, till the mucus has thoroughly penetrated the part, and afterwards to wash with sea-water. Or otherwise, to gather two pounds of the tumid vesicles, in the month of July, when they are full of mucus, and infuse them in a quart of sea-water, in a glass-veffel, for the space of 15 days, when the liquor will have acquired nearly the consistence of honey. Then strain it off through a linen cloth, and rub this liquor with the hand, as before, three or four times a-day upon any hard or serophulous swellings, washing, the

parts afterwards with sea-water, and nothing can be more efficacious to disperse them. Even scirrhoties, he says, in women's breasts, have been dispelled by this treatment.

The same author, by calcining the plant in the open air, made a very black salt powder, which he called *vegetable athrops*; a medicine much in use as a resolvent and deobstruent, and recommended also as an excellent dentrifice, to correct the scorbutic laxity of the gums, and take off the foulness of the teeth.

3. The plicatus, matted, or Indian-grass fucus, grows on the sea-shores in many places both of Scotland and England. It is generally about three or four, but sometimes six inches long. Its colour, after being exposed to the sun and air, yellowish, or auburn. Its substance pellucid, tough, and horny, so as to bear a strong resemblance to what the anglers call *Indian grass*, that is, the tendrils issuing from the ovary of the dog-fish.

4. The palmatus, palmated, or sweet fucus, commonly called *dulse*, or *dissle*. This grows plentifully on the sea-coasts of Scotland, and the adjoining islands. Its substance is membranaceous, thin, and pellucid; the colour red, sometimes green with a little mixture of red; its length generally about five or six inches, but varies from three inches to a foot; its manner of growth fan-shaped, or gradually dilated from the base upwards. Its divisions extremely various. The inhabitants both of Scotland and England take pleasure in eating this plant, without expecting any medical virtues from it. The inhabitants of the Archipelago also are fond of this plant, as we learn from Steller. They sometimes eat it raw, but esteem it most when added to ragouts, ogleis, &c. to which it gives a red colour; and, dissolving, renders them thick and gelatinous. In the Isle of Skye it is sometimes used in fevers to promote a sweat, being boiled in water with the addition of a little butter. In this manner it also frequently purges. The dried leaves, infused in water, exhale the scent of violets.

5. The esculentus, eatable fucus, or bladderlocks, commonly called *langle* in Scotland, is likewise a native of the British shores. It is commonly about four feet long, and seven or eight inches wide, but is sometimes found three yards or more in length, and a foot in width. Small specimens are not above a cubit long, and two inches broad. The substance is thin, membranaceous, and pellucid; the colour green or olive. The root consists of tough, cartilaginous fibres. The stalk is about six inches long, and half an inch wide, nearly square, and pinnated in the middle, between the root and origin of the leaf, with ten or a dozen pair of thick, cartilaginous, oval-obtus, foliaceous ligaments, each about two inches long, and crowded together. The leaf is of an oval-lanceolate, or long elliptic form, simple and undivided, waved on the edges, and widely ribbed in the middle from bottom to top, the stalk running through its whole length, and standing out on both sides of the leaf. This fucus is eaten in the north both by men and cattle. Its proper season is in the month of September, when it is in greatest perfection. The membranous part is rejected, and the stalk only is eaten. It is recommended in the disorder called a *piea*, to strengthen the stomach and restore the appetite.

6. The *saccharinus*, sweet fucus, or sea-belt, is very common on the sea-coast. The substance of this is cartilaginous and leathery; and the leaf is quite ribbed. By these characters it is distinguished from the preceding, to which it is nearly allied. It consists only of one simple, linear, elliptic leaf, of a tawny green colour, about five feet long, and three inches wide, in its full-grown state; but varies so exceedingly as to be found from a foot to four yards in length. The ordinary length of the stalk is two inches, but it varies even to a foot. The root is composed of branched fibres, which adhere to the stones like claws. This plant is often infested with the *tertiaria ciliata*.

The inhabitants of Iceland make a kind of pottage of this fucus; boiling it in milk, and eating it with a spoon. They also soak it in fresh water, dry it in the sun, and then lay it up in wooden vessels, where in a short time it is covered with a white efflorescence of sea-salt, which has a sweet taste like sugar. This they eat with butter; but if taken in too great a quantity, the salt is apt to irritate the bowels and bring on a purging. Their cattle feed and get fat upon this plant, both in its recent and dry state; but their flesh acquires a bad flavour. It is sometimes eaten by the common people on the coast of England, being boiled as a pot-herb.

6. The *ciliatus*, ciliated, or ligulated fucus, is found on the shores of Jona and other places, but is not common. The colour of this is red, the substance membranous and pellucid, without rib or nerve; the ordinary height of the whole plant about four or five inches. It is variable in its appearance, according to the different stages of its growth. This fucus is eaten by the Scotch and Irish promiscuously with the *fucus palmatus* or *dilse*.

7. The *prolifer*, or *proliferous fucus*, is found on the shores of the western coast, adhering to shells and stones. The colour is red; the substance membranaceous, but tough, and somewhat cartilaginous, without rib or nerve, though thicker in the middle than at the edges. The whole length of the plant is about four or five inches, the breadth of each leaf about a quarter of an inch. The growth of this fucus, when examined with attention, appears to be extremely singular and wonderful. It takes its origin either from a simple, entire, narrow, elliptic leaf, about an inch and a half long; or from a dilated forked one, of the same length. Near the extremity of the elliptic leaf, or the points of the forked one, (but out of the surface, and not the edge), arises one or more elliptic or forked leaves, which produce other similar ones, in the same manner, near the summits; and so on continually one or more leaves from near the ends of each other, in a *proliferous* and *dichotomous* order, to the top of the plant; which in the manner of its growth resembles in a good measure the *cactus opuntia*, or flat-leaved Indian fig. Sometimes two or three leaves, or more, grow out of the middle of the disc of another leaf; but this is not the common order of their growth. The fructifications are red, spherical, rough warts, less than the smallest pin's head, scattered without order on the surface of the leaves. These warts, when highly magnified, appear to be the curled rudiments of young leaves; which in due time either drop off and form new plants, or continue on and germinate upon

the parent. This plant is very much infested with the *flustra pilosa*, the *madrepora verrucaria*, and other corallines, which make it appear as if covered with white scabs.

8. The *pinnatifidus*, jagged fucus, or pepper-dilse, is frequent on sea-rocks which are covered by the tides, both on the eastern and western coasts. It is of a yellow olive-colour, often tinged with red. The substance is cartilaginous, but yet tender and transparent; the height about two or three inches. This fucus has a hot taste in the mouth, and is therefore called *pepper-dilse* by the people in Scotland, who frequently eat it as a salad in the same manner they do the *fucus palmatus*.

9. The *plocamium*, or *pectinated fucus*, is frequent on the sea-rocks, and in basins of water left by the recess of the tides. Its natural colour is a most beautiful bright red or purple, but is often variegated with white or yellow. Its substance is cartilaginous, but extremely thin, delicate, and transparent. Its height commonly about three or four inches. The stalk is compressed, about half a line in diameter, erect, but waved in its growth, and divided almost from the base into many widely expanded branches. These primary branches are very long, alternate, exactly like the stalk, and subdivided into alternate secondary branches, which are again frequently compounded in like manner, and these divisions decorated with subulated teeth growing in alternate rows, curiously pectinated or finely toothed on the upper side like a comb, the smallest of these teeth scarcely visible to the naked eye. The fructifications are minute spherical capsules, or smooth dark-red globules, scattered without order on the sides of the branches; generally sessile, but some few of them supported on short peduncles. This fucus, on account of its elegant colours and fine divisions, is the species most admired by the ladies who are fond of pictures and mimic landscapes composed of marine vegetables.

10. The *filum*, *thread-fucus*, or *sea-laces*, is found on the sea-rocks, and waving under the water like long strings, frequent on many parts of the coast. The substance of this is opaque and cartilaginous, but not difficult to be broken. The colour, when recent, a dull olive-green; when dry, fuscous, or nearly black; and when exposed for some time on the shores to the sun and air, it becomes yellow, straw-coloured, or white. It consists only of a simple, unbranched, naked, cylindrical stalk, three or four yards long, more or less, from the size of a large fiddle-string to that of a thick whip-cord; smallest at the base and summit; smooth on the outside, full of mucus within; often twisted, and always intercepted by numerous transverse diaphragms, visible when the plant is held between the eye and the light. The fructifications have not yet been discovered; but from the transverse septa in its structure, it is reasonable to suppose this plant to belong rather to the genus of *conferva* than that of *fucus*. The stalks, skinned when half dry and twisted, acquire so considerable a degree of strength and toughness, that we were informed the Highlanders sometimes used them for the same intentions as Indian grass.

11. The *giganteus*, or *gigantic fucus*, is a native of the Straits Le Maire; and grows on rocky ground, which in those countries is distinguished from sand or

gora
adens.

ooze by the enormous length of the sea-weeds that grow upon it. The leaves are four feet long, and some of the stalks, though not thicker than a man's thumb, are 120. Mr Banks and Dr Solander found over some of them which were 84 feet long; and as they made a very acute angle with the bottom, they were thought to be at least one half longer.

FULGORA, in zoology, a genus of insects belonging to the order of hemiptera; the characters of which are, The front, or fore-part of the head, is drawn extended and empty. The antennæ are seated below the eyes, having two articulations, whereof the exterior is larger, and of a globular form. The rostrum is inflected, or bent inwards under the body. The feet are made for walking. There are nine species, the most remarkable of which is the lanternaria. See **LANTERN-FLY**, (*Encycl.*) and Plate CCCXIII.

FUNGI, (*Encycl.*) The piperatus, or pepper-agaric, though the most acrid and suspicious of the whole tribe, is eaten in great quantities by the Russians. They fill large vessels with them in the autumn, season or pickle them with salt, and eat them in the ensuing Lent. But as the free use of these and others of the genus has frequently been attended with fatal consequences, it may not be amiss in this place, once for all, to admonish the reader of the general nature and dangerous qualities of them; which we cannot do better than in the words of the great and ingenious Haller. "All fungi are crude in their nature, of speedy growth and sudden decay. They spring up, arrive at maturity, and perish in a few days, most of them dissolving away in a black corrupted liquor, of a fetid nauseous smell. They are the food of snails, beetles, flies, maggots, and the nidus where they deposit their young.

"The Russians indeed devour almost every species, even those which other nations esteem the most poisonous, such as the agaricus muscarius, piperatus, &c.; but all of them are a doubtful and suspicious food, and the most innocent have proved sometimes prejudicial.

"By analysis it is found, that seven parts of eight in their composition are watery. They yield by fire a yellow spirit like hartshorn, a yellow empyreumatic oil, and a dry, volatile, crystalline salt; so that their nature is evidently alkaline, extremely prone to corruption.

"Their fibres are tough and very difficult to digest, swelling in the stomach like a sponge; so that there are instances of their remaining undigested for three

days before their bad effects have appeared. The maladies they occasion are, a swelling of the abdomen, restlessness, heartburns, vomitings, colics, difficult breathings, hiccoughs, melancholy, diarrhæas accompanied with a tenesmus, and gangrenes. To which dreadful complaints the acrimonious quality of some fungi bring on, besides, inflammations in the mouth, with bloody lotions and bloody stools. Lastly, it is certain that some species have an intoxicating quality, followed often by deliriums, tremblings, watchings, faintings, apoplexies, cold sweats, and death itself. Some have fancied that skilful cookery would deprive them of their bad effects, and that oils would steal their noxious qualities; but these are fatal deceits, not to be trusted.

"To persons suffering from eating any species of fungi, the most approved and speedy remedy is to use emetics and cathartics."

FURIA, in zoology, a genus of insects belonging to the order of vermes zoophyta. There is but one species, viz. the infernalis. This has a linear smooth body ciliated on each side, with reflexed feelers pressed to its body. In Finland, Bothnia, and the northern provinces of Sweden, it was not infrequently that people were seized with a pungent pain, confined to a point, in the hand or other exposed part of the body, which presently increased to a most excruciating degree, and hath sometimes been suddenly fatal. This disorder was more particularly observed in Finland, especially about boggy and marshy places, and always in autumn. At length it was discovered that this pain instantly succeeded somewhat that dropped out of the air, and in a moment penetrated and buried itself in the flesh. The Finlanders had tried variety of applications to no purpose, until at length a poultice of curds or cheese was found the most effectual in easing the pain: and the event confirmed that the insect was allured by this application to leave the flesh; as, on its removal, this worm, no longer than the sixth of an inch, was found in it, and thus the cause of this painful disease explained. But by what means this creature is raised into the air, is as yet unknown.

FUST, (*Encycl.*) Line 5. for 1460, read 1443; and line 67. for "their types were cut in wood and fixed, not moveable as at present;" read "they used separate wooden types, or cut metal types, of which Guttemberg was the inventor." See *History of PRINTING*, (*Encycl.*)

GÆLIC LANGUAGE. For See **GÆLIC** in *Appendix*, read See **HIGHLANDS**.

GARDENS (**HANGING**), in antiquity, gardens raised on arches by Nebuchadnezzar king of Babylon, in order to gratify his wife Amyctis, daughter of Astyages king of Media. Q. Curtius makes them equal in height to the walls of the city, viz. 50 feet. They contained a square of 400 feet on every side, and were carried up into the air in several terrasses laid above one another, and the ascent from terrass to terrass was by stairs 10 feet wide. The arches sustaining the whole pile were raised above one another, and it was

strengthened by a wall, surrounding it on every side, of 22 feet in thickness. The floors of each of the terrasses were laid in the following manner: on the top of the arches were first laid large flat stones 16 feet long and 4 broad, and over them was a layer of reed mixed with a great quantity of bitumen, over which were two rows of bricks closely cemented together by plaster, and over all were laid thick sheets of lead; and lastly, upon the lead was laid the mould of the garden. The mould or earth was of such a depth as to admit the largest trees to take root and grow; and it was covered with various kinds of trees, plants, and flowers.

Gas,
Gaubius.

flowers. In the upper terrais there was an aqueduct or engine, whereby water was drawn up out of the river for watering the whole garden.

GAS, (*Encycl.*) The composition of aerial vapours or gases, is a subject which has drawn the attention of the curious, though little can be known with precision. What can be known with any degree of probability is drawn entirely from the effects of latent heat upon terrestrial bodies. By means of this element almost all substances become for a time aeriform; and if they do not constantly remain so, it is because of their inability to absorb the heat in a permanent manner. From analogy, however, we must be apt to conclude, that those aerial fluids which continue permanently elastic are formed in like manner by the union of a vast quantity of latent heat with some small portion of terrestrial matter, in such a manner that they cannot afterwards be separated, at least so easily as the latent heat of mere aqueous or other vapours is absorbed. This will be in some measure confirmed by the two following considerations. 1. There is no kind of aerial vapour which does not expand by heat to a very great degree. Terrestrial bodies, whose texture is close and compact, expand but little by heat. These, we know, are formed of a great quantity of inactive matter, together with a very fine invisible fluid with which their pores are filled. The expansion probably takes place by means of an agitation in this fluid excited by heat. Air is exceedingly expandible; whence its terrestrial particles are probably few in number, while the quantity of fluid interposed betwixt them is very great. 2. All kinds of air seem to be produced from some terrestrial matter and heat, at least heat in some way or other seems to be concerned in the formation of all that are yet known. In the first process published by Dr Priestley for making dephlogisticated air, a violent heat was employed. Oil of vitriol poured on red-lead was afterwards found to yield dephlogisticated air also: but the red-lead had been previously subjected to a strong heat; and, even in the very act of producing the air, a great degree of heat is spontaneously generated. In the natural processes for producing dephlogisticated air, the *light* of the sun, and consequently his heat, in some degree is necessary for its formation. Besides, all the different airs or gases we know, fixed air, inflammable, nitrous, marine acid, vitriolic acid, fluor acid, vegetable acid, phlogisticated airs, &c. are every one of them produced from terrestrial materials. In these materials we know that an invisible fluid, the same with elementary heat or fire, is continually acting; whence it is exceedingly probable that all of these vapours are nothing else than combinations of the two.

GAUBIUS (Hieronymus David), a celebrated physician of Holland, studied under the illustrious Boerhaave; and became so much the favourite of his professor, that he resigned the chemical chair in his favour. He taught at Leyden with great applause for 40 years. In the year 1775 he laid down his office, as being no longer able to support the fatigues of it. He was succeeded by John David Hahn, then professor at Utrecht. His reputation was extended all over Europe by several valuable publications, particularly by his *Institutiones Pathologiae Medicinalis*, and his *Adversaria*, which have contributed not a little to the improvement both of the theory and practice of medi-

cine. He died at Leyden 29th November 1780, in General Gentoos

the 76th year of his age.
GENERATION OF INSECTS. The world is now generally convinced, that insects are not bred of corruption, but *ex ovo*; though the contrary was believed by the ancients, because of the vast numbers that were sometimes hatched, as it were at once, and because they could not discern the particular manner of their propagation.

Malpighi, Swammerdam, and Redi, have abundantly disproved the doctrine of equivocal generation, as well as the chimerical transformation of the caterpillar into the butterfly, and other the like metamorphoses; and have shown, that all the members of the butterfly were originally inclosed under the skin or nymph of the caterpillar, as the parts of a plant are in the seed.

Insects take particular care to deposit their eggs or seed in such places where they may have a sufficient incubation, and where the young, when hatched, may have the benefit of proper food till they become able to shift for themselves. Those whose food is in the water, lay their eggs in the water; those to whom flesh is a proper food, in flesh; and those to whom the fruits or leaves of vegetables are food, are accordingly deposited, some in this fruit, some in that tree, and some in one plant, and some in another; but constantly the same kind in the same tree or plant. As for others that require a more constant and greater degree of warmth, they are provided by the parent animal with some place in or about the body of other animals; some in the feathers of birds, some in the hair of beasts; some in the scales of fishes, some in the nose, some in the flesh, nay, some in the bowels and inmost recesses of man and other creatures. And as for others, to whom none of those methods are proper, the parents make them nests by perforation in the earth, in woods, in combs, and the like; carrying in and sealing up provisions that serve both for the production of their young, and for their food, when produced. In flies, butterflies, &c. it is observed, there is a kind of gluten, by which the female fastens her eggs to the bearing buds of trees, &c. so that the rains cannot wash them off. These eggs will not be hurt by the greatest frost.

GENTOOS, in modern history, according to the common acceptance of the term, denote the professors of the religion of the bramins or brachmans, who inhabit the country called *Hindustan*, in the East Indies, from the word *stan*, a "region," and *hind* or *hindoo*; which Ferishteh, as we learn from colonel Dow's translation of his history, supposes to have been a son of Ham the son of Noah. It is observed, however, that Hindoo is not the name by which the inhabitants originally styled themselves; but, according to the idiom of the *schanferit* which they use, *jumbodeep*, from *jumboo*, a "jackall," an animal common in their country; and *deep*, a large portion of land surrounded by the sea; or *berttekhunt*, from *khunt*, i. e. a "continent," and *bherryhut*, the name of one of the first Indian rajahs. It is also to be observed, that they have assumed the name of Hindoos only since the era of the Tartar government, to distinguish themselves from their conquerors the Mussulmans. The term *Gentoo* or *Gent*, in the Shanferit dialect, denotes animal in general, and in its more confined sense mankind, and is never

never appropriated particularly to such as follow the doctrines of Brhima. These are divided into four great tribes, each of which has its own separate appellation; but they have no common or collective term that comprehends the whole nation under the idea affixed by the Europeans to the word *Gentoo*. Mr Halhed, in the preface to his translation of the Code of G-ntoo Laws, conjectures, that the Portuguese, on their first arrival in India, hearing the word frequently in the mouths of the natives, as applied to mankind in general, might adopt it for the domestic appellation of the Indians themselves, or perhaps their bigotry might force from the word *Gentoo* a fanciful allusion to Gentile or Pagan. The Hindoos, or Gentoos, vie with the Chinese as to the antiquity of their nation. They reckon the duration of the world by four jogues, or distinct ages: the first is the Suttie jogue, or age of purity, which is said to have lasted about 3,200,000 years; during which the life of man was 100,000 years, and his stature 21 cubits: the second, the Tirtah jogue, or the age in which one-third of mankind were reprobate; which consisted of 2,400,000 years, when men lived to the age of 10,000 years: the third, the Dwapar jogue, in which half of the human race became depraved; which endured to 600,000 years, when mens lives were reduced to 1000 years: and fourthly, the Collee jogue, in which all mankind were corrupted, or rather diminished, which the word *collee* imports. This is the present æra, which they suppose will subsist for 400,000 years, of which near 5000 are already past; and man's life in this period is limited to 100 years. It is supported by many authors, that most of the *Gentoo shasters*, or scriptures, were composed about the beginning of the *collee jogue*: but an objection occurs against this supposition, viz. that the shasters take no notice of the deluge; to which the bramins reply, that all their scriptures were written before the time of Noah, and the deluge never extended to Hindostan. Nevertheless, it appears from the shasters themselves, that they claim a much higher antiquity than this; instances of which are recited by Mr Halhed.

The doctrine of transmigration is one of the distinguishing tenets of the Gentoos. With regard to this subject, it is their opinion, according to Mr Holwell, that those souls which have attained to a certain degree of purity, either by the innocence of their manners or the severity of their mortifications, are removed to regions of happiness proportioned to their respective merits; but that those who cannot so far surmount the prevalence of bad example, and the powerful degeneracy of the times, as to deserve such a promotion, are condemned to undergo continual punishment in the animation of successive animal-forms, until, at the stated period, another renovation of the four jogues shall commence, upon the dissolution of the present. They imagine six different spheres above this earth; the highest of which, called *suttie*, is the residence of Brhima and his particular favourites. This sphere is also the habitation of those men who never uttered a falsehood, and of those women who have voluntarily burned themselves with their husbands; the propriety of which practice is expressly enjoined in the code of the *Gentoo laws*. This code, printed by the East-India Company in 1776, is a very curious collection

of Hindoo jurisprudence, which was selected by the most experienced pundits or lawyers, from curious originals in the Shanferit language, who were employed for this purpose from May 1773 to February 1775; afterwards translated into the Persian idiom, and then into the English language, by Mr Halhed.

The several institutes contained in this collection are interwoven with the religion of the Gentoos, and revered as of the highest authority. The curious reader will discover an astonishing similarity between the institutes of this code and many of the ordinances of the Jewish law; between the character of the bramins or priests, and the Levites; and between the ceremony of the scape-goat under the Mosaic dispensation, and a *Gentoo* ceremony called the *assumed jug*, in which a horse answers the purpose of the goat. Many obsolete customs and usages alluded to in many parts of the Old Testament, may also receive illustration from the institutes of this code. It appears from the code, that the bramins, who are the priests and legislators of the country, have resigned all the secular and executive power into the hands of another cast or tribe; and no bramin has been properly capable of the magistracy since the time of the *suttie jogue*. The only privilege of importance which they have appropriated to themselves, is an exemption from all capital punishment: they may be degraded, branded, imprisoned for life, or sent into perpetual exile; but it is every where expressly ordained, that a bramin shall not be put to death on any account whatsoever.

We have already observed, that the Hindoos are divided into four great and original tribes, which, according to the *Gentoo* theology, proceeded from the four different members of Brhima, the supposed immediate agent of the creation under the spirit of the Almighty. These tribes are the bramins, which proceeded from his mouth, and whose office is to pray, read, and instruct; the Chesterke, which proceed from his arms, whose office is to draw the bow, to fight, and to govern; the Bice, proceeding from the belly or thighs, who are to provide the necessaries of life by agriculture and traffic; and the Sooder, from the feet, which are ordained to labour, serve, and travel.

Few Christians, says the translator of the *Gentoo* code, have expressed themselves with a more becoming reverence of the grand and impartial designs of Providence in all its works, or with a more extensive charity towards all their fellow-creatures of every profession, than the Gentoos. It is indeed an article of faith among the bramins, that God's all-merciful power would not have permitted such a number of different religions, if he had not found a pleasure in beholding their varieties.

GEOFFRÆA, in botany, a genus of the decandria order, belonging to the diadelphia class of plants. There is only one species, viz. the cabbage-bark tree. The wood of this tree is used in building; but it is chiefly valued for its bark, which is administered in different forms, viz. in decoctions, syrup, powder, and extract, as an anthelmintic medicine. From this medicinal property it is also called the *worm-bark tree*. The decoction made by boiling an ounce of the bark in a quart of water, is mostly used in Jamaica; and it seldom fails to perform every thing that can be expected from an anthelmintic medicine, by destroying

Gentoos,
Geoffræa.

Geography worms in the intestines, and bringing them away in great quantities. This bark is externally of a grey colour, and internally black and furrowed; its taste, when fresh, is mucilaginous and sweet; and its smell, which it retains in the decoction, disagreeable. Dr Wright of Jamaica recommends it as a very valuable remedy.

GEOGRAPHY. At n° 33. dele *Plate CXVI.* fig. 2. on the margin; and at the end of the section add, "See Plate XLVIII. fig. 2. and **ASTRONOMY**, p. 802."

GILLICRANKY. See **GILLICRANKY**, (*Encycl.*) **GLOSSOPETRA.** or **GLOTOPETRA**, in natural history, a kind of extraneous fossil, somewhat in form of a serpent's tongue; frequently found in the island of Malta, and divers other parts. See *Plate CCCXVII.*

The vulgar notion is, that they are the tongues of serpents petrified; and hence their name, which is a compound of γλῶσσα, "tongue," and πέτρα, "stone." Hence also their traditional virtue in curing the bites of serpents. The general opinion of naturalists is, that they are the teeth of fishes, left at land by the waters of the deluge, and since petrified.

The several sizes of the teeth of the same species, and those of the several different species of sharks, afford a vast variety of these fossil substances. Their usual colours are black, bluish, whitish, yellowish, or brown; and in shape they usually approach to a triangular figure. Some of them are simple; others are tricuspidate, having a small point on each side of the large one: many of them are quite straight; but they are frequently found crooked, and bent in all directions; many of them are serrated on their edges, and others have them plain; some are undulated on their edges, and slightly serrated on these undulations. They differ also in size as much as in figure; the larger being four or five inches long, and the smaller less than a quarter of an inch.

They are most usually found with us in the strata of blue clay, though sometimes also in other substances, and are frequent in the clay-pits of Richmond and other places. They are very frequent also in Germany, but nowhere so plentiful as in the island of Malta.

The Germans attribute many virtues to these fossil teeth; they call them cordials, sudorifics, and alexipharmics: and the people of Malta, where they are extremely plentiful, hang them about their childrens necks to promote dentition. They may possibly be of as much service this way as an anodyne necklace; and if suspended in such a manner that the child can get them to its mouth, may, by their hardness and smoothness, be of the same use as a piece of coral.

GNAT. (*Encycl.*) Line 1. for *See Musca*, read "*See CULEX in the APPENDIX.*"

GORDON (Alexander), an excellent draughtsman, and a good Grecian, who resided many years in Italy, visited most parts of that country, and had also travelled into France, Germany, &c. was secretary to the Society for Encouragement of Learning; and afterwards to the Egyptian Club, composed of gentlemen who had visited Egypt (viz. Lord Sandwich, Dr Shaw, Dr Pococke, &c.) He succeeded Dr Stukely as secretary to the Antiquarian Society, which office he resigned in 1741 to Mr Joseph Ames. He

went to Carolina with governor Glen, where, besides a grant of land, he had several offices, such as register of the province, &c.; and died a justice of the peace, leaving a handsome estate to his family. He published, 1. "Itinerarium Septentrionale, or a Journey through most parts of the Counties of Scotland, in two parts, with 66 copperplates, Lond. 1726," folio. 2. "Additions and Corrections, by way of Supplement, to the Itinerarium Septentrionale; containing several Disquisitions on, and Descriptions of, Roman Antiquities, discovered in Scotland since publishing the said Itinerary. Together with Observations on other ancient Monuments found in the North of England, never before published. Lond. 1732," folio. 3. "The Lives of Pope Alexander VI. and his son Cesar Borgia, comprehending the wars in the reign of Charles VIII. and Lewis XII. kings of France; and the chief Transactions and Revolutions in Italy, from the year 1492 to the year 1516." 4. "A complete History of the ancient Amphitheatres, more particularly regarding the Architecture of these Buildings, and in particular that of Verona, by the marquis Scipio Maffei; translated from the Italian, 1730," 8vo. afterwards enlarged in a second edition. 5. "An Essay towards explaining the hieroglyphical figures on the Coffin of the ancient Mummy belonging to Captain William Lethieuller. Lond. 1737," folio, with cuts. 6. "Twenty-five plates of all the Egyptian Mummies, and other Egyptian Antiquities in England," about 1739, folio.

GORDONIA, **LOBLOLLY-BAY**, a genus of the polyandria order, belonging to the monodelphia class of plants. This is a tall and very straight tree, with a regular pyramidal head. Its leaves are shaped like those of the common bay, but serrated. It begins to blossom in May, and continues bringing forth its flowers the greatest part of the summer. The flowers are fixed to foot-stalks, four or five inches long; are monopetalous, divided into five segments, encompassing a tuft of stamina headed with yellow apices; which flowers, in November, are succeeded by a conic capsula having a divided calix. The capsula, when ripe, opens, and divides into five sections, disclosing many small half-winged seeds. This tree retains its leaves all the year, and grows only in wet places, and usually in water. The wood is somewhat soft; yet Mr Catfish mentions his having seen some beautiful tables made of it. It grows in Carolina, but not in any of the more northern colonies.

GORGONIA, in natural history, a name given by some writers to coral, on occasion of its supposed change from a soft substance to an absolute stone, on being brought out of the water into the air: but this is known now to be a fabulous opinion, coral being as hard while growing to the rocks as when it has been ever so long out of the sea.

The gorgonizæ are a genus of zoophytes, which formerly were called *ceratophyton*, and are known in English by the names of *sea fans*, *sea feathers*, and *sea-whips*. Dr Linnæus and Dr Pallas consider them as of a mixed nature in their growth, between animals and vegetables; but Mr Ellis has clearly proved that they are true animals of the polype kind, growing up in a branched form resembling a shrub, and in no part vegetable. They differ from the fresh-water polype

Gordon
Gorge

in many of its qualities, and particularly in producing from its own substance a hard and solid support, serving many of the purposes of the bone in other animals. This is formed by a concreting juice thrown out from a peculiar set of longitudinal parallel tubes, running along the internal surface of the fleshy part: in the coats of these tubes are a number of small orifices, through which the osseous liquor exudes, and, concreting, forms the layers of that part of the hard annular circles which some, judging from the consistence rather than the texture, have erroneously denominated wood. The surface of the gorgonia is composed of a kind of scales, so well adapted to each other as to serve for defence from external injuries: and the flesh, or, as some have called it, the *bark* or *cortex*, consists of proper muscles and tendons for extending the openings of their cells, for sending forth from thence their polype suckers in search of food, and for drawing them in suddenly and contracting the sphincter muscles of these fleshy cells, in order to secure these tender parts from danger; and also of proper secretory ducts, to furnish and deposit the osseous matter that forms the stem and branches as well as the base of the bone. Mr Ellis affirms, that there are ovaries in these animals, and thinks it very probable that many of them are viviparous.

GRASS, (*Enyel.*) By grasses are meant all those plants which have a round, jointed, and hollow stem, surrounded at each joint with a single leaf, long, narrow, and pointed, and whose seeds are contained in chaffy husks. It appears by this definition, which is Ray's, that all the kinds of grain, as wheat, oats, barley, &c. are properly grasses; and that the broad, the white, the hop, &c. clovers are not grasses, though so frequently called by that name.

Culmiferous grasses might be divided into two general classes for the purposes of the farmer, that it might be of use for him to attend to; viz. 1st, Those which, like the common annual kinds of corn, run chiefly to seed-stalks; the leaves gradually decaying as these advance towards perfection, and become totally withered or fall off entirely when the seeds are ripe. Rye-grass belongs to this class in the strictest sense. To it likewise may be assigned the vernal-grass, dogs-tail-grass, and fine bent-grass. 2^{dly}, Those whose leaves continue to advance even after the seed-stalks are formed, and retain their verdure and succulence during the whole season, as is the case with the fescue and poa tribe of grasses, whose leaves are as green and succulent when the seeds are ripe and the flower-stalks fading, as at any other time.

“ It is wonderful, Mr Stillingfleet † remarks, to see how long mankind has neglected to make a proper advantage of plants of such importance, and which, in almost every country, are the chief food of cattle. The farmer, for want of distinguishing and selecting grasses for seed, fills his pastures either with weeds or bad or improper grasses; when, by making a right choice, after some trials, he might be sure of the best grass, and in the greatest abundance that his land admits of. At present, if a farmer wants to lay down his land to grass, what does he do? he either takes his seeds indiscriminately from his own foul hay-rick, or sends to his next neighbour for a supply. By this means, besides a certain mixture of all sorts of rubbish,

which must necessarily happen, if he chances to have a large proportion of good seeds, it is not unlikely but that what he intends for dry land may come from moist, where it grew naturally, and the contrary. This is such a slovenly method of proceeding, as one would think could not possibly prevail universally: yet this is the case as to all grasses except the daniel-grass, and what is known in some few counties by the name of the *Suffolk grass*; and this latter instance is owing, I believe, more to the soil than any care of the husbandman. Now, would the farmer be at the pains of separating once in his life half a pint or a pint of the different kinds of grass-seeds, and take care to sow them separately, in a very little time he would have wherewithal to stock his farm properly, according to the nature of each soil, and might at the same time spread these seeds separately over the nation, by supplying the seed-shops. The number of grasses fit for the farmer is, I believe, small, perhaps half a dozen or half a score are all he need to cultivate; and how small the trouble would be of such a task, and how great the benefit, must be obvious to every one at first sight. Would not any one be looked on as wild who should sow wheat, barley, oats, rye, pease, beans, vetches, buck-wheat, turneps, and weeds of all sorts together? yet how is it much less absurd to do what is equivalent in relation to grasses? Does it not import the farmer to have good hay and grass in plenty? and will cattle thrive equally on all sorts of food? We know the contrary. Horses will scarcely eat hay that will do well enough for oxen and cows. Sheep are particularly fond of one sort of grass, and fatten upon it faster than any other, in Sweden, if we may give credit to Linnaeus. And may they not do the same in Britain? How shall we know till we have tried?”

As the generality of farmers know scarce any of the grasses by name, and as without such knowledge little improvement can be made in this branch of husbandry, we have on Plate CCCXIX. given figures of those sorts which have been recommended as the most profitable, viz.

1. *Hordeum murinum*, RYE-GRASS *vulgo*. [Rye-grass *proprie* is the *secale villosum*. Perennial daniel, *lolium perenne*, is also, in some counties of England, improperly called *rye-grass*.]

2. *Festuca rubra*, PURPLE FESCUE-GRASS. See AGRICULTURE, n° 52.

3. *Festuca ovina*, SHEEPS ditto. See AGRICULTURE, n° 54.

4. *Holcus lanatus*, CREEPING SOFT-GRASS. See AGRICULTURE, n° 57.

5. *Aspercurus bulbosus*, BULBOUS FOXTAIL-GRASS, is recommended by Mr Anderson †, as promising on † *Essays on* some occasions to afford a valuable pasture-grass. It Agriculture, &c. seems chiefly, he observes, to delight in a moist soil, and therefore promises to be only fit for a meadow pasture-grass. The quality that first recommended it to his notice, was the unusual firmness that its matted roots gave to the surface of the ground, naturally soft and moist, in which it grew; which seemed to promise that it might be of use upon such soils, chiefly in preventing them from being much poached by the feet of cattle which might pasture upon them. Mossy soils especially are so much hurt by poaching, that any thing that promises to be of use in preventing it deserves to be attended to.

6. *Poa pratensis*, GREAT MEADOW-GRASS, seems to approach in many respects to the nature of the purple-fescue; only that its leaves are broader, and not near so long; being only about a foot or 16 inches at their greatest length. Like it, it produces few seed-stalks and many leaves, and is an abiding plant.

7. *Poa compressa*, CREEPING MEADOW-GRASS, according to Mr Anderson, seems to be the most valuable grass of any of this genus. Its leaves are firm and succulent, of a dark Saxon-green colour; and grow so close upon one another, as to form the richest pile of pasture-grass. The flower-stalks, if suffered to grow, appear in sufficient quantities; but the growth of these does not prevent the growth of the leaves, both advancing together during the whole summer; and when the stalks fade, the leaves continue as green as before. Its leaves are much larger and more abundant than the common meadow-grass, *poa trivialis*; and therefore it better deserves to be cultivated.

8. *Anthoxanthum odoratum*, VERNAL GRASS, grows very commonly on dry hills, and likewise on found rich meadow-land. It is one of the earliest grasses we have; and from its being found on such kinds of pastures as sheep are fond of, and from whence excellent mutton comes, it is most likely to be a good grass for sheep-pastures. It gives a grateful odour to hay. It is very easy to gather, as it sheds its seeds upon the least rubbing.

9. *Cynosurus cristatus*, CRESTED DOG'S-TAIL GRASS. Mr Stillingfleet imagines this grass to be proper for parks, from his having known one, where it abounds, that is famous for excellent venison. He recommends it also, from experience, as good for sheep; the best mutton he ever tasted, next to that which comes from hills where the purple and sheeps fescue, the fine bent, and the silver hair grasses abound, having been from sheep fed with it. He adds that it makes a very fine turf upon dry sandy or chalky soils: but unless swept over with the scythe, its flowering-stems will look brown; which is the case of all grasses which are not fed on by variety of animals. For that some animals will eat the flowering-stems is evident by commons, where scarcely any parts of grasses appear but the radical leaves.

10. *Stipa pennata*, COCK'S-TAIL or FEATHER GRASS.

11. *Agrostis capillaris*, FINE BENT, is recommended by Mr Stillingfleet, from his having always found it in great plenty on the best sheep-pastures, in the different counties of England that are remarkable for good mutton.

12. *Areira flexuosa*, MOUNTAIN HAIR.

13. — *caryophylla*, SILVER HAIR.

The same may be said of these two grasses as of the preceding one.

14. *Festuca siliensis*, FLOTE FESCUE. In a piece published in the *Amœnitates Academicæ*, vol. 3. intitled *Plantæ Esculentæ*, we are informed, that "the seeds of this grass are gathered yearly in Poland, and from thence carried into Germany, and sometimes into Sweden, and sold under the name of *manna seeds*. These are much used at the tables of the great, on account of their nourishing quality and agreeable taste. It is wonderful, (adds the author), that amongst us these seeds have hitherto been neglected, since they are so easily collected and cleaned." There is a clammy-

ness on the ear of the flote-fescue, when the seeds are ripe, that tastes like honey; and for this reason perhaps they are called *manna seeds*.

Linnaeus (*Flor. Suec.* art. 95.) says that the bran of this grass will cure horses troubled with botts, if kept from drinking for some hours.

Concerning this grass we have the following information by Mr Stillingfleet. "Mr Dean, a very sensible farmer at Rusbomb, Berkshire, assured me that a field, always lying under water, of about four acres, that was occupied by his father when he was a boy, was covered with a kind of grass, that maintained five farm-horses in good heart from April to the end of harvest, without giving them any other kind of food, and that it yielded more than they could eat. He, at my desire, brought me some of the grass, which proved to be the flote-fescue with a mixture of the marsh-bent; whether this last contributes much towards furnishing so good pasture for horses, I cannot say. They both throw out roots at the joints of the stalks, and therefore likely to grow to a great length. In the index of dubious plants at the end of Ray's Synopsis, there is mention made of a grass under the name of *gramen caninum supinum longissimum*, growing not far from Salisbury, 24 feet long. This must by its length be a grass with a creeping stalk; and that there is a grass in Wiltshire growing in watery meadows, so valuable, that an acre of it lets from 10 to 12 pounds, I have been informed by several persons. These circumstances incline me to think it must be the flote-fescue; but whatever grass it be, it certainly must deserve to be inquired after."

15. *Alopecurus pratensis*, MEADOW FOXTAIL. Linnaeus says that this is a proper grass to sow on grounds that have been drained.—Mr Stillingfleet was informed, that the best hay which comes to London is from the meadows where this grass abounds. It is scarce in many parts of England, particularly Herefordshire, Berkshire, and Norfolk. It might be gathered at almost any time of the year from hay-ricks, as it does not shed its seeds without rubbing, which is the case of but few grasses. It is amongst the most grateful of all grasses to cattle.

16. *Poa annua*, ANNUAL MEADOW GRASS. "This grass (says Mr Stillingfleet) makes the finest of turfs. It grows every where by way sides, and on rich found commons. It is called in some parts the *Suffolk grass*. I have seen whole fields of it in High Suffolk without any mixture of other grasses; and as some of the best salt-butter we have in London comes from that county, it is most likely to be the best grass for the dairy. I have seen a whole park in Suffolk covered with this grass; and whether it affords good venison, I cannot tell, having never tasted of any from it. I should rather think not, and that the best pasture for sheep is also the best for deer. However, this wants trial. I remarked on Malvern-hill something particular in relation to this grass. A walk that was made there for the convenience of the water-drinkers, in less than a year was covered in many places with it, though I could not find one single plant of it besides in any part of the hill. This was no doubt owing to the frequent treading, which above all things makes this grass flourish; and therefore it is evident that rolling must be very serviceable to it.

"It has been objected, that this grass is not free from botts,

Harmattan *bents*, by which word is meant the flowering-stems. I answer, that this is most certainly true, and that there is no grass without them. But the flowers and stems do not grow so soon brown as those of other grasses; and being much shorter, they do not cover the radical leaves so much; and therefore this grass affords a more agreeable turf without mowing, than any other whatever that I know of."

GROWTH, (*Encycl.*) See also NUTRITION, (*Encycl.*)

Growth
|
Herb.

GUIDON, in ancient military history, the name of a sort of standard carried by the king's life-guards; so called from its being broad at one extreme, almost pointed at the other, and slit or divided in two.

GUNNERY. P. 4543. marginal note, n° 15. for Plate CXLIV. read Plate CXLII.

H.

HARMATTAN, a very extraordinary kind of wind and fog on the coast of Guinea, of which an account, taken from Dr Lind's works, is given under the article *MEDICINE*, p. 4657. col. 2. An account remarkably different, however, from that of the Doctor, may be seen in the *Philosophical Transactions*, vol. lxxi.

HEAT, (*Encycl.*) See also PHLOGISTON, (*Encycl.*)
HEBRIDES. P. 3556. col. 2. line 2. for *MULK* read *MULL*.

HEDGE-NETTLE, the *flachys sylvatica*. Horses abominate this plant. Cows, notwithstanding its fetid smell, will eat it; and Gunner says it undoubtedly increases their milk greatly.

HEDGE-SPARROW, a species of *MOTACILLA*, omitted under that article. Its head is of a deep brown, mixed with ash-colour; the cheeks marked with oblong spots of dirty white: the back and coverts of the wings are dusky, edged with reddish brown; the quill-feathers and tail dusky: the rump brown, tinged with green: the throat and breast are of a dull ash-colour; the belly of a dirty white: the sides, thighs, and vent-feathers are of a pale tawny brown; the legs of a dull flesh-colour.—This bird frequents low hedges, especially those of gardens. It makes its nest in some small bush, and lays four or five eggs of a fine pale-blue colour; during the breeding season it has a remarkable flirt with its wings. The male has a short but very sweet plaintive note, which it begins with the first frosty mornings, and continues till a little time in the spring. This is the *motacilla modularis* of Linnaeus; the bird which he supposes to be our hedge-sparrow, and describes under the title of *motacilla curruca*, differs in colours of plumage as well as eggs.

HEIR-LOOMS, (*Encycl.*) See *Heir-Looms*, (*Encycl.*)
HELM. For Plate CXLVIII. read CLVIII.

HEMERIOBIUS, (*Encycl.*) This insect takes the name of *hemerobius* from the shortness of its life, which, however, continues several days. In the state of larva it is a great devourer of plant-lice, for which it has had bestowed upon it the appellation of *lion of the plant-lice*. The *hemerobii*, even after their transformation, preserve their carnivorous inclination. Not satisfied with making war upon the plant-lice, who tamely let themselves be devoured, they do not spare each other. The eggs of this insect are borne upon small pedicles, which are nothing but a gum spun out by the *hemerobius* by raising up the hinder-part of its abdomen, and by that means the egg remains fastened to the upper part of the thread. Those eggs are deposited upon leaves, and set in the form of bunches. They have been taken for parasitic plants. The larva, when hatched, finds there its food in the midst of plant-lice. In 15 or 16 days it has attained

to its full growth. With its spinning-wheel at its tail, it makes itself a small, round, white, silky cod, of a clove texture. In summer, at the end of three weeks, the *hemerobius* issues forth with its wings; but when the cod has not been spun till autumn, the *chrysalis* remains in it the whole winter, and does not undergo its final metamorphose till the ensuing spring. The flight of this insect is heavy: some species have an excrementitious smell. One goes by the name of the *water-hemerobius*, because it lives mostly at the water-side.

HEMSKERCK (Egbert), called the *Old*, a celebrated Flemish painter of drolls and conversations, of whom, though so universally known, we have no information as to the time in which he flourished, or the school in which he was taught. Though the taste of his compositions is but low, yet it ought to be considered that he took his subjects from nature; from persons in the meanest occupations, whose dress, actions, and manners, could not furnish the imagination with any ideas of elegance: and to express their passions and undisguised humours, seems to have been the utmost of his ambition. By frequenting fairs, merry-meetings, gaming-houses, and inns, he acquired a surprising power of connecting humorous circumstances; he designed and drew correctly, and his pictures have a strong effect from his accurate management of the chiaro oscuro. Some of his pictures have suffered from unskilful cleaners, and many things are sold as his which dishonour him; but his genuine works, well preserved, have a clearness and force equal to any of the Flemish artists.

HEMSKERCK (Egbert), called the *Young*, was the disciple of Peter Grebber, but imitated the manner of Brouwer and of the elder Hemskerck. He was born at Haarlem in 1645, but settled at London, where for a long time his works were exceedingly esteemed, tho' they are now much sunk in their value. He had a whimsical imagination, and delighted in composing uncommon and fanciful subjects; such as the temptation of St Anthony, nocturnal intercourses of witches and spectres, enchantments, &c. which he executed with a free pencil and a spirited touch. It was customary with him to introduce his own portrait among the conversations he designed; and for that purpose had a small looking-glass placed near his case. He died in 1704.

HERALDRY. P. 3593. col. 2. for 19 *argent*, read 20 *argent*.

HERB-ROBERT. This plant is in great reputation with some farmers on account of its prevailing virtues against staling of blood, and the bloody-flux in cattle; in which cases it is said to be the best among a great variety of means commonly used on these occasions.

Heriot.
Hooke.

HERIOT, in law, a customary tribute of goods and chattels, payable to the lord of the fee on the decease of the owner of the land. See **TENURE**, (*Encycl.*)

Heriot is of two sorts—viz. 1. *Heriot*-custom, where heriots have been paid time out of mind by custom, after the death of a tenant for life. In some places, there is a customary composition in money, as 10 or 20 shillings in lieu of a heriot, by which the lord and tenant are both bound, if it be an indispensible ancient custom; but a new composition of this sort will not bind the representatives of either party. 2. *Heriot*-service, when a tenant holds by such service to pay heriot at the time of his death; which service is expressed in the deed of feoffment.—For this latter the lord shall distrain; and for the other he shall seize, and not distrain. If the lord purchase part of the tenancy, heriot-service is extinguished; but it is not so of heriot-custom.

HERNANDIA, (*Encycl.*) The sonora is a native of Java, and other parts of the East Indies. It affords a sure antidote against poison, if you either put its small roots on the wounds or eat them; as was discovered to Rumphius by a captive woman in the war between the people of Macassar and the Dutch in the year 1667. The soldiers of the former always carry this root about them, as a remedy against wounds with poisonous arrows. The leaves of this tree are thick and smooth. Another tree like this, which likewise grew here, had not such thick and smooth leaves.

HINDOOS. See **GENTOOS** in this APPENDIX.

HIRUNDO. P. 3647. col. 2. dele l. 4.

HOLOTHURIA, in zoology, a genus belonging to the order of vermes mollusca. There are nine species, all inhabitants of the ocean. The physalis, called by the Dutch *bessantjes*, by Dampier *cutters*, and by the English sailors *man-of-war*, has a half-round body, stands directly upwards, has many long and many short tentacula, is slimy, transparent, somewhat bluish, shines in dark nights, is poisonous, and so light that it will scarce sink in Spanish brandy. Beyond the Cape they are small; in the ocean they are larger and very numerous, especially in March.

HOOKE (Nathaniel), author of an esteemed Roman history and other performances.—Of this learned gentleman the earliest particulars to be met with are furnished by himself, in the following modest but mainly address to the Earl of Oxford, dated Oct. 7. 1722: "My Lord, the first time I had the honour to wait upon your Lordship since your coming to London, your lordship had the goodness to ask me, what way of life I was then engaged in; a certain *mauvais honte* hindered me at that time from giving a direct answer. The truth is, my lord, I cannot be said at present to be in any form of life, but rather to live extempore. The late epidemical distemper seized me, I endeavoured to be rich, imagined for a while that I was, and am in some measure happy to find myself at this instant but just worth nothing. If your Lordship, or any of your numerous friends, have need of a servant, with the bare qualifications of being able to read and write, and to be honest, I shall gladly undertake any employments your Lordship shall not think me unworthy of. I have been taught, my lord, that neither a man's natural pride, nor his self-love, is an equal

Hooke.

judge of what is fit for him; and I shall endeavour to remember, that it is not the short part we act, but the manner of our performance, which gains or loses us the applause of him who is finally to decide of all human actions. My lord, I am just now employed in translating from the French, a History of the Life of the late archbishop of Cambray; and I was thinking to beg the honour of your lordship's name to protect a work which will have so much need of it. The original is not yet published. 'Tis written by the author of the "Discourse upon Epic Poetry," in the new edition of *Telemaque*. As there are some passages in the book of a particular nature, I dare not solicit your lordship to grant me the favour I have mentioned, till you first have perused it. The whole is short, and pretty fairly transcribed. If your lordship could find a spare hour to look it over, I would wait upon your lordship with it, as it may possibly be no unpleasing entertainment. I should humbly ask your lordship's pardon for so long an address in a season of so much business. But when should I be able to find a time in which your lordship's goodness is not employed? I am, with perfect respect and duty, my lord, your lordship's most obliged, most faithful, and most obedient humble servant, **NATHANIEL HOOKE**." The translation here spoken of was afterwards printed in 12mo, 1723. From this period till his death, Mr Hooke enjoyed the confidence and patronage of men not less distinguished by virtue than by titles. In 17... he published a translation of Ramfay's Travels of Cyrus, in 4to; in 1733 he revised a translation of "The History of the Conquest of Mexico by the Spaniards, by Thomas Townsend, Esq;" printed in 2 vols 8vo; and in the same year he published in 4to, the first volume of "The Roman History, from the building of Rome to the ruin of the Commonwealth; illustrated with maps and other plates." In the dedication to this volume, Mr Hooke took the opportunity of "publicly testifying his just esteem for a worthy friend, to whom he had been long and much obliged," by telling Mr Pope, that the displaying of his name at the head of those sheets was "like the hanging out a splendid sign, to catch the traveller's eye, and entice him to make trial of the entertainment the place affords. But," he proceeds, "when I can write under my sign, that Mr Pope has been here, and was content, who will question the goodness of the house?" The volume is introduced by "Remarks on the History of the Seven Roman Kings, occasioned by Sir Isaac Newton's objections to the supposed 244 years duration of the royal state of Rome." His nervous pen was next employed in digesting "An Account of the conduct of the Dowager-duchess of Marlborough, from her first coming to Court to the Year 1710. In a Letter from herself to Lord —. 1742." 8vo. His reward on this occasion was considerable; and the reputation he acquired by the performance much greater. The circumstances of this transaction are thus related by Dr Maty, in his *Memoirs of Lord Chesterfield*, vol. i. p. 116. "The relict of the great duke of Marlborough, being desirous of submitting to posterity her political conduct, as well as her lord's, applied to the earl of Chesterfield for a proper person to receive her information, and put the memoirs of her life into a proper dress.

drefs. Mr Hooke was recommended by him for that purpose. He accordingly waited upon the duchess, while she was still in bed, oppressed by the infirmities of age. But, knowing who he was, she immediately got herself lifted up, and continued speaking during six hours. She delivered to him, without any notes, her account, in the most lively as well as the most connected manner. As she was not tired herself, she would have continued longer the business of this first sitting, had not she perceived that Mr Hooke was quite exhausted, and wanted refreshment as well as rest. So eager was she for the completion of the work, that she insisted upon Mr Hooke's not leaving her house till he had finished it. This was done in a short time; and her Grace was so well pleased with the performance, that she complimented the author with a present of 5000*l.* a sum which far exceeded his expectations. As soon as he was free, and permitted to quit the house of his benefactors, he hastened to the earl, to thank him for his favour, and communicated to him his good fortune. The perturbation of mind he was under, occasioned by the strong sense of his obligation, plainly appeared in his flammering out his acknowledgments: and he, who had succeeded so well as the interpreter of her Grace's sentiments, could scarcely utter his own." The second volume of his "Roman history" appeared in 1745; when Mr Hooke embraced the fair occasion of congratulating his worthy friend the earl of Marchmont, on "that true glory, the consenting praise of the honest and the wise," which his lordship had so early acquired. To the second volume Mr Hooke added "The Capitoline Marbles, or Consular Calendars, an ancient Monument accidentally discovered at Rome in the year 1545, during the Pontificate of Paul III." In 1758 Mr Hooke published "Observations on, I. The Answer of M. l'Abbe de Vertot to the late earl of Stanhope's Inquiry concerning the Senate of ancient Rome: dated December, 1719. II. A Dissertation upon the Constitution of the Roman Senate, by a Gentleman: published in 1743. III. A Treatise on the Roman Senate, by Dr Conyers Middleton: published in 1747. IV. An Essay on the Roman Senate, by Dr Thomas Chapman: published in 1750;" which he with great propriety inscribed to Mr Speaker Onslow. The third volume of Mr Hooke's "Roman History," to the end of the Gallic war, was printed under his inspection before his last illness; but did not appear till after his death, which happened in 1764. The fourth and last volume was published in 1771. Mr Hooke left two sons; of whom one is a divine of the church of England; the other, a doctor of the Sorbonne, and professor of astronomy in that illustrious seminary.

HOPE, in ethics, is the desire of some good, attended with a belief of the possibility, at least, of obtaining it, and enlivened with joy, greater or less, according to the greater or less probability of our possessing the object of our hope. Alexander, preparing for his Asian expedition, distributed his hereditary dominions among his friends; allotting to some villages, to others boroughs, to others cities; and being asked what he had reserved for himself, replied, Hope.

HOPS. See HUMULUS, (*Encycl.*) The cultivation of hops, which is now so very general, is not in

all places equally successful. Very large hop-grounds will for 20 years successively appear with the most promising verdure, yet produce nothing. When the fructification in an early state contracts a mouldiness, it withers and is destroyed. It is then infested by the aphides, who produce on it what is commonly called an *honey-dew*; but the plant must first be in a sickly state before it is infested with these insects. Into this situation it is reduced by the caterpillar of the phalaena humuli or other moth, which feeds on its roots; a circumstance of which the cultivators of this plant are generally ignorant, though some of them have discovered that a sound hop will be infested by planting a sickly one near it, when they transplant the roots from a hop-ground that is thus attacked to one that is perfectly healthy. The hop grows naturally among stones and fragments of rocks, where it is never damaged by the honey-dew. The reason is, that the caterpillar abovementioned, cannot in such a soil penetrate to its roots; and therefore, those who cultivate this plant ought to cover the ground with stones.

HUMMING-BIRD. See TROCHILUS, (*Encycl.*) We have the following pleasing account of this little animal in professor Kalm's Travels into America. The description applies to the *trochilus colubris* †. "Its † See Plate plumage is most beautifully coloured, most of its feathers being green, some grey, and others forming a shining red ring round its neck; the tail glows with fine feathers, changing from green into a brass colour. These birds come here (Pennsylvania) in spring, about the time when it begins to grow very warm, and make their nests in summer; but towards autumn, they retreat again into the more southern countries of America. They subsist barely upon the nectar, or sweet juice of flowers, contained in that part which botanists call the *nectarium*, and which they suck up with their long bills. Of all the flowers, they like those most which have a long tube; and they are observed to flutter chiefly about the *impatiens noli tangere*, and the *monarda* with crimson flowers. An inhabitant of the country is sure to have a number of these beautiful and agreeable little birds before his windows all the summer long, if he takes care to plant a bed with all sorts of fine flowers under them. The flowers of the above-mentioned monarda grow verticillated, that is, at different distances they surround the stalk, as the flowers of our mint (*mentha*), bastard hemp (*galteopsis*), mother-wort (*leonurus*), and dead nettle (*lamium*). It is therefore diverting to see them putting their bills into every flower in the circle. As soon as they have sucked the juice of one flower, they flutter to the next. One that has not seen them would hardly believe in how short a space of time they have had their tongues in all the flowers of a plant, which when large, and with a long tube, the little bird, by putting its head into them, looks as if it crept with half its body into them.

"During their sucking the juice out of the flowers, they never settle on it, but flutter continually like bees, bend their feet backwards, and move their wings so quick, that they are hardly visible. During this fluttering, they make a humming like bees, or like that which is occasioned by the turning of a little wheel. After they have thus, without resting, fluttered for a while, they fly to a neighbouring tree or post, and resume their vigour again. They then re-

turn:

Humming-
Bird.

Humming, turn to their humming and sucking. When several of
Hunter. them were on the same bed, there was always a violent
combat between them, in meeting each other at the
same flower (for envy was likewise predominant a-
mongst these little creatures), and they attacked with
such impetuosity, that it would seem as if the strongest
would pierce its antagonist through and through with
its long bill. During the fight, they seem to stand in
the air, keeping themselves up by the incredibly swift
motion of their wings. When the windows towards
the garden are open, they pursue each other into the
rooms, fight a little, and flutter away again. Some-
times they come to a flower which is withering, and
has no more juice in it; they then, in a fit of anger,
pluck it off and throw it on the ground, that it may
not mislead them for the future. If a garden contains
a great number of these little birds, they are seen to
pluck off the flowers in such quantities, that the ground
is quite covered with them, and it seems as if this pro-
ceeded from a motion of envy.

“Commonly you hear no other sound than their hum-
ming; but when they fly against each other in the air,
they make a chirping noise like a sparrow or chicken.
They are so small, that one would easily mistake them
for great humble-bees or butterflies; and their flight
resembles that of the former, and is incredibly swift.
They have never been observed to feed on insects or
fruit; the nectar of flowers seems therefore to be their
only food. Several people have caught some hum-
ming-birds, on account of their singular beauty, and
have put them into cages, where they died for want
of a proper food. However, Mr Bartram has kept a
couple of them for several weeks together, by feeding
them with water in which sugar had been dissolved;
and I am of opinion, that it would not be difficult to
keep them all winter in a hot-house.

“The humming-bird always builds its nest in the
middle of a branch of a tree; and it is so small, that it
cannot be seen from the ground, but he who intends
to see it must get up to the branch. For this reason
it is looked upon as a great rarity if a nest is accident-
ally found, especially as the trees in summer have so
thick a foliage. The nest is quite round, and con-
sists in the inside of a brownish and quite soft down,
which seems to have been collected from the leaves of
the great mullein or *verbascum thapsus*, which are of-
ten found covered with a soft wool of this colour, and
the plant is plentiful here: other materials, however,
are often used, as flax, hemp, moss, hair, or such like
soft substances. The outside of the nest has a coating of
green moss, such as is common on old pales, or en-
closures, and on trees; the inner diameter of the nest
is hardly a geometrical inch at the top, and its depth
half an inch; they are said to lay two eggs, each of
the size of a pea.”

HUNTER (Dr William), a celebrated anatomist,
was a native of Kilgerie in the county of Lanerk in
Scotland. Being designed by his father for the church,
he was sent, at a proper age, to the college of Glasgow:
But having spent five years in regular academical at-
tendance there, he began to feel strong objections to
theological studies; and happening to become ac-
quainted with Dr Cullen, who was at that time just
established in practice at Hamilton, he was per-

suaded to apply himself to physic. Dr Cullen's
friendship made it easy to obtain his father's consent.
He was taken into the DoRor's house, where he
spent two of the happiest years of his life. In
Scotland (if we except Edinburgh) there is not that
distinction between the branches of physic that prevails
in England. The physicians generally dispense their
own medicines, and likewise practise surgery. Dr
Cullen, though an enthusiastic cultivator of physic and
chemistry, had always a dislike to the chyrurgical part
of his practice. It was therefore agreed between him
and Mr Hunter, that the latter should go first to the
college at Edinburgh, and then to London, in order
to see the practice of the hospitals, and improve him-
self in anatomy and surgery, and that at his return to
Hamilton a partnership should take place between them.
Mr Hunter brought with him to London a letter of
introduction to his countryman Dr James Douglas, at
that time in high reputation as a physician and man-
midwife, and well known by his “Treatise on the
Muscles,” and other works. Dr Douglas advised him
to attend St George's Hospital, and Dr Nichols's lec-
tures, as a perpetual pupil, for the opportunity of
learning all his arts in making anatomical preparations.
At the end of the season, when he was preparing
to set out on his return to Hamilton, Dr Douglas per-
suaded him to change his proposed plan; to assist him
in his anatomical pursuits; to accompany his son, at
that time a student in physic, to Paris and Holland;
and afterwards to settle in London, and to teach ana-
tomy. Mr Hunter communicated this proposal, and
the arguments which Dr Douglas had used, to Dr
Cullen; who, thinking it a fairer prospect, with his
usual generosity readily gave his consent. After the
death of his patron Dr Douglas, Mr Hunter began
to teach anatomy in London. His easy, agreeable
manner of lecturing, the new and clear points of view
in which he placed the different parts of his subject,
added to the number and elegance of his preparations,
drew to him a great number of pupils. He soon be-
came eminent in his profession, and enriched the art
with many important discoveries. In or about 1747, Mr
Hunter was admitted a member of the Surgeon's com-
pany. His anatomical reputation soon procured him an
extensive practice, particularly in midwifery; and when
he came to be established, the university of Glasgow
complimented him with the degree of M. D. In 1756
he was admitted a member of the College of Physicians;
and soon afterwards was elected F. R. S. having made
himself known by an ingenious paper “on the Structure
of Cartilages,” published in the Phil. Trans. so early as
1743. He since, at different times, communicated several
other valuable papers to the society. When the
present queen became pregnant, Dr Hunter was con-
sulted, and at the same time honoured with the ap-
pointment of physician-extraordinary to her majesty.
When the Royal Academy of Arts was founded, he
was nominated professor of anatomy to that institu-
tion; and lately, upon the death of one of the eight
foreign associates of the Academy of Sciences at Paris,
he was elected to supply the vacancy. To consider
him as a teacher, is to view him in his most amiable
character: perspicuity, unaffected modesty, and a de-
sire of being useful, were his peculiar characteristics;
and,

Hunter.

Ichneumon.

and, of all others, he was most happy in blending the *utile* with the *dulce*, by introducing apocryphal and pleasing stories to illustrate and enliven the more abstruse and jejune parts of anatomy; thus fixing the attention of the volatile and the giddy, and enriching the minds of all with useful knowledge. Employed as Dr Hunter had been, for a long series of years, by persons of the highest rank in this country, and consulted as an anatomist in difficult cases of surgery by all ranks of people and from every part of the kingdom, his gains must have been immense; and he employed them in a manner of all others the most liberal, the improvement of science. Having never married, and being averse to ostentation and luxury, he always conducted his domestic expences on a plan adapted to his profession; and his accumulated fees were expended in erecting and furnishing a museum, which, considered in every point of view, is certainly not to be equalled in Europe. It is unnecessary to say any thing of the anatomical varieties it contains, because it will be easily conceived, that a person of the Doctor's disposition, who had spent near half a century in the pursuit of a favourite object, must have amassed every thing that is curious and valuable on that subject. But the specimens of human and comparative anatomy form only a small part of the Hunterian Museum. The collection of scarce and valuable books is to be equalled only by royal libraries; and his cabinet of medals, particularly Greek and Roman, is far more valuable than the Imperial collection at Vienna. The expence of building his house and museum in Windmill-street, and furnishing the latter, is said to have approached near to 100,000*l*. His Plates of the Gravid Uterus, and his other publications, sufficiently evince his profound knowledge and unwearied industry; and the description of his Greek coins his boundless munificence. It is much to be feared that the other works he had in hand at the time of his death are left too incomplete for the public eye. His museum, the most comprehensive and select of any individual's in Europe, was left for thirty years to his sister's son, Mr Bailey. If during the above-

mentioned period of 30 years Mr Bailey should die, the property of the museum for the remainder of the period devolves to Mr Cruikshank. At the conclusion of the period of 30 years, the entire museum, without any participation or entail whatever, is bequeathed to the university of Glasgow. The sum of 4000*l*. sterling is left, with the interest from time to time growing on it, for the support and augmentation of the collection. His brother, Mr John Hunter, the surgeon, on account of some difference between them; is not named in the will. The executors are, Dr Pitcairn, Mr Coombe apothecary (the Doctor's learned coadjutor in his literary labours), and Dr Fordyce of Essex-street; to each of whom Dr Hunter has left a legacy of 20*l*. a-year, during the period in which they will be executing the purposes of the will. Making a pecuniary estimate of the museum in question, 70,000*l*. is said to be the sum it is worth. Besides that, the Doctor was possessed of above 20,000*l*. in money; the bulk of which is given to Mr Bailey. We are credibly informed, that the Doctor formerly applied to the ministers of this country to allot him a piece of ground, on which he might build a museum, that he would engage to leave endowed for the public service. His request, however, was not complied with; and he then purchased the premises in Great Windmill-street, where he built his museum and spacious habitation. He died 30th April 1783, of the gout in his stomach.

HYDRA, in zoology, a genus of the order of zoophyta, belonging to the class of vermes. There are seven species, known by the general name of polypes. See POLYPE, in this APPENDIX.

HYDROCEPHALUS INTERNUS; (*Encycl.*) See MEDICINE, n° 370. 438. Besides the use of mercury, there recommended as effectual in this disease, formerly so fatal, a surprising instance of the efficacy of the vapour-bath is given in the 8th volume of the Medical Commentaries. The instance, however, is singular, and the medicine ought to be often repeated with success before much confidence is put in it.

Plate
CCCXXII.

JACEA, in botany. See CENTAUREA, (*Encycl.*)

JAGO (Richard), an ingenious poet, was vicar of Snitterfield in Warwickshire, and rector of Kimcote in Leicestershire. He was the intimate friend and correspondent of Mr Shenstone, contemporary with him at Oxford, and, it is believed, his schoolfellow; was of University College; took the degree of M.A. July 9. 1739; was author of several poems in the 4th and 5th volumes of Doddley's Poems; published a sermon, in 1755, on the Causes of Impenitence considered, preached May 4. 1755, at Harbury in Warwickshire, where he was vicar, on occasion of a conversation said to have passed between one of the inhabitants and an apparition in the church-yard there; wrote "Edge-hill," a poem, for which he obtained a large subscription in 1767; and was also author of "Labour and Genius, 1768," 4to; of "The Blackbirds," a beautiful elegy in the Adventurer; and of many other ingenious performances. He died May 28. 1781.

ICHNEUMON, (*Encycl.*) One distinguishing and

striking character of these species of flies is the almost continual agitation of their antennæ. The name of *ichneumon* has been applied to them from the service they do us by destroying caterpillars, plant-lice, and other insects, as the *ichneumon* or mangouste destroys the crocodiles. The variety to be found in the species of *ichneumons* is prodigious: among the smaller species, there are males who perform their amorous preludes in the most passionate and gallant manner. The posterior part of the females is armed with a whimble, visible in some species, nowise discoverable in others; and that instrument, though so fine, is able to penetrate through mortar and plaster: the structure of it is more easily seen in the long-whimbled fly. The food of the family to be produced by this fly is the larva of wasps or mason-bees; for it no sooner espies one of those nests, but it fixes on it with its whimble, and bores through the mortar of which it is built. The whimble itself, of an admirable structure, consists of three pieces: two collateral ones, hollowed out into a gutter, serve as a sheath, and contain a compact, solid,

solid, dentated stem, along which runs a groove that conveys the egg from the animal, who supports the whimble with its hinder legs, lest it should break; and by a variety of movements, which it dexterously performs, it bores through the building, and deposits one or more eggs, according to the size of the ichneumon, though the largest drop but one or two. Some agglutinate their eggs upon caterpillars; others penetrate through the caterpillar's eggs, though very hard, and deposit their own on the inside. When the larva is hatched, its head is so situated, that it pierces the caterpillar, and penetrates to its very entrails. These larvæ pump out the nutritious juices of the caterpillar, without attacking the vitals of the creature; who appears healthy, and even sometimes transforms itself to a chrysalis. It is not uncommon to see those caterpillars fixed upon trees, as if they were sitting upon their eggs, and it is afterwards discovered that the larvæ, which were within their bodies, have spun their threads, with which, as with cords, the caterpillars are fastened down, and so perish miserably. The ichneumons performed special service in the years 1731 and 1732; by multiplying in the same proportion as did the caterpillars, their larvæ destroyed more of them than could be effected by human industry. Those larvæ, when on the point of turning into chrysalids, spin a silky cocoon. Nothing is more surprising and singular, than to see those cods leap, when placed on the table or hand. Plant-lice, the larvæ of the curculiones, spiders' eggs, are also sometimes the cradle of the ichneumon-fly. Carcases of plant-lice, void of motion, are often found on rose-tree leaves: they are the habitation of a small larva, which, after having eaten up the entrails, destroys the springs and inward economy of the plant-louse, performs its metamorphose under shelter of the pellicle which enfolds it, contrives itself a small circular outlet, and sallies forth into open air. There are ichneumons in the woods, who dare attack spiders, run them through with their sting, tear them to pieces, and thus avenge the whole nation of flies of so formidable a foe: others, destitute of wings, (and those are females) deposit their eggs in spiders' nests. The ichneumon of the bedeguar (or sweet-briar sponge), and that of the rose-tree, perhaps only deposit their eggs in those places, because they find other insects on which they feed. The genus of the ichneumon flies, might with propriety be termed a race of diminutive cannibals.

ICHTHYOLOGY, (Encycl.) The most judicious arrangement of this branch of Zoology seems to be that of Mr Pennant, who distributes fish into three divisions; *Cetaceous, Cartilaginous, and Bony.*

Div. I. CETACEOUS Fish; the characters of which are the following: No gills; an orifice on the top of the head, through which they breathe and eject water; a flat or horizontal tail; exemplified in Plate CCCXVIII. (lower compartment), fig. 1. by the Beaked Whale, borrowed from Dale's Hist. Harw. 411. Tab. xiv.—This division comprehends three genera; the Whale, Cachalot, and Dolphin.

Div. II. CARTILAGINOUS Fish; the characters of which are: Breathing through certain apertures, generally placed on each side the neck; but in some instances beneath, in some above, and from one to seven in number on each part, except in the pipe-fish, which

has only one; the muscles supported by cartilages instead of bones. Example, the Picked Dog-fish, fig. 2. **a.** The lateral apertures.—The genera are, the Lamprey, Skate, Shark, Fishing-frog, Surgeon, Sun-fish, Lump-fish, Pipe-fish.

Div. III. BONY Fish, includes those whose muscles are supported by bones or spines, which breathe thro' gills covered or guarded by thin bony plates, open on the side, and dilatable by means of a certain row of bones on their lower part, each separated by a thin web; which bones are called the *radii branchiifleggi*, or the *gill covering rays*. The tails of all the fish that form this division are placed in a situation perpendicular to the body; and this is an invariable character.

The great sections of the Bony Fish into *Apodal, Thoracic, Jugular, and Abdominal*, he copies from Linnaeus: who founds this system on a comparison of the ventral fins to the feet of land-animals or reptiles; and either from the want of them, or their particular situation in respect to the other fins, establishes his sections.—In order to render them perfectly intelligible, it is necessary to refer to those several organs of movement, and some other parts, in a perfect fish, or one taken out of the three last sections. In fig. 4. (the Haddock), *a*, is the pectoral fins; *b*, ventral fins; *c*, anal fins; *d*, caudal fin, or the tail; *e, e, e*, dorsal fins; *f*, bony plates that cover the gills; *g*, branchiostegous rays and their membranes; *h*, lateral or side line.

SECT. 1. APODAL: The most imperfect, wanting the ventral fins; illustrated by the Conger, fig. 3. This also expresses the union of the dorsal and anal fins with the tail, as is found in some few fish.—Genera: The Eel, Wolf-fish, Lance, Morris, Sword-fish.

SECT. 2. JUGULAR: The ventral fins *b*, placed before the pectoral fins *a*, as in the Haddock, fig. 4.—Genera: The Dragonet, Weaver, Codfish, Blenny.

SECT. 3. THORACIC: The ventral fins *a*, placed beneath the pectoral fins *b*, as in the Father Lasher, fig. 5.—Genera: The Goby, Bull-head, Doree, Flounder, Gilt-head, Wraite, Perch, Stickleback, Mackerel, Surmullet, Gurnard.

SECT. 4. ABDOMINAL: The ventral fins placed behind the pectoral fins, as in the Minnow, fig. 6.—Genera: The Loche, Salmon, Pike, Argentine, Athérine, Mullet, Flying fish, Herring, Carp.

ICHTHYPERIA, (Encycl.) See Plate CCCXVII. **IDEAS, (Encycl.)** The origin of ideas has been a long time disputed among philosophers. The Peripatetics maintain, that external objects emit species which resemble them all around; and that these species, striking on our senses, are by them transmitted to the understanding; and that, being material and sensible, they are rendered intelligible by the active intellect; and are at length received by the passive. Others are of opinion, that our souls have of themselves the power of producing ideas of things we would think upon; and that they are excited to produce them by the impressions which objects make on the body, tho' these impressions are not images in any respect like the objects that occasioned them. And in this, say they, it is, that man is made after the image of God, and that he partakes of his power; for as God made all things out of nothing, and can reduce them to nothing when he pleases, so man can create as many ideas as he pleases, and annihilate them when he has done.

Others

Others maintain, that the mind has no occasion for any thing beside itself to perceive objects; and that, by considering itself, and its own perfections, it is able to discover all things that are without. Others, with Des Cartes, hold, that our ideas were created and born along with us.

Malebranche, and his followers, assert, that God has in himself the ideas of all the beings he has created; that thus he sees all things, in considering his own perfections, to which they correspond; and that, as he is intimately united to our souls, by his presence, our mind sees and perceives things in him which represent created beings; and that it is thus we come by all our ideas. He adds, that though we see all sensible and material things in God, yet that we have not our sensations in him. When we perceive any sensible object, in our perception is included both a sensation and a pure idea. The sensation is a modification of the soul, and it is God who causes it in us: but for the idea joined with the sensation, it is in God; and it is in him that we see it.

The Cartesians distinguish three kinds of ideas. The first, innate; such, they say, is that we have of God, as of a Being infinitely perfect. The second, adventitious; which the mind receives in proportion as bodily objects present themselves to our senses: such is the idea of body, sound, figure, light, &c. The third, according to these philosophers, are fæctitious; which are those which the mind forms, by uniting and assembling the ideas which it already had; and these are called *complex*. But Mr Locke seems to have put this matter out of dispute; having made it appear, that all our ideas are owing to our senses; and that all innate, created, and fæctitious ideas, are mere chimeras.

Our mind, he shows, has not absolutely any ideas besides those presented to it by the senses, and those which it forms by its own operations on those others which the senses furnish; so that a man, destitute of one of his senses, would never have any idea belonging to that sense; and, supposing him destitute of all the senses, he would never have any idea at all: external objects having no other way of producing ideas in him, but by means of sensation, he would have no idea, not even of reflection; because, in wanting all sensation, he wants that which would excite in him the operations of his mind, which are the objects of his reflection.

It is plain, therefore, there is no innate idea; no general truth, or first principle, inherent in the soul, and created with it; no immediate object of the mind, before it had perceived external objects by means of the senses, and reflected on that perception. Those ideas only seem to be innate, because we find we have them as soon as we come to the use of reason; but they are, in effect, what we formed from the ideas wherewith the mind was insensibly filled by the senses. Thus, when the mind is employed about sensible objects, it comes by the ideas of bitter, sweet, yellow, hard, &c. which we call *sensation*; and, when employed about its own operations, perceiving and reflecting on them, as employed about the ideas before got by sensation, we get the ideas of perception, thinking, doubting, willing, &c. which we call *inward sensation*, or *reflection*; and these two, viz. external material

things as the objects of sensation, and the operations of our own minds as the objects of reflection, are the only originals whence all our ideas have their rise. When we have considered these, and their several modes and combinations, we shall find, that they contain our whole stock of ideas, inasmuch that the understanding does not seem to have the least glimmering of any ideas, that it did not receive from one of those sources.

And thus far the mind appears merely passive, as not having it in its power to choose whether it will have these first beginnings, or materials of knowledge, or not. For the objects of sense will obtrude their ideas upon the mind; and the operations of the mind will not let us be without some (however obscure) notion of them.

The origin of our ideas and notions is a perplexed question, and not at all cleared up by the labours of metaphysicians. As to ideas of sense, some philosophers have pretended, that bodies acting or pressing upon our nerves, or putting the animal-spirits in motion, produce sensations; but as the motion communicated to the nerves or spirits has nothing in common either with the thing or body moving, or with the idea excited in the mind, and that we do not conceive the least relation between the motion of the nerves or spirits and the production of an idea; to say that the motion of, or impression upon, the nerves or animal-spirits is the cause of ideas, is explaining nothing at all.

The species emitted by objects, and the formation of ideas by the soul itself, are not more clear. As to innate ideas, it is true indeed, that the arguments of those who maintain them, have been refuted by Mr Locke; but when he goes farther, and denies innate ideas, his arguments have been thought by some not to be conclusive.

Dr Price, in his Inquiry into the Original of our Ideas, has taken occasion to remark, that the system of Mr Locke, which ascribes all our ideas to sensation and reflection, is materially defective; for, if by sensation we understand the effects arising from the impressions made on our minds by external objects, and by reflection the notice which the mind takes of its own operations, it will be impossible to drive some of the most important of our ideas from them. This excellent reasoner observes, that the power within us that understands, the intuition of the mind, or the faculty in it that discerns truth, that views, compares, and judges of all ideas and things, is a spring of new simple ideas, or original, primary, and uncompounded perceptions of the mind. To this source he refers our ideas of the impenetrability and *vis inertia* of matter, substance, duration, space, infinity, necessity, contingency, possibility, impossibility, power, causation, &c. all our abstract ideas, and also our ideas of moral right and wrong, and of moral obligation. It is, he says, of the essence of these ideas to imply something true or false of an object, and that they by no means denote the manner in which we are affected by it; so that they cannot with any propriety be referred to that part of our constitution, which has been distinguished by the appellation of *sense*. Accordingly, our ideas may be divided, first, into those implying nothing real without the mind, or nothing real and true besides its own affections and passions: to which class we may refer the immediate effects of impressions on the bodily senses,

Ideas,

senses, without supposing any previous ideas; as all tastes, smells, colours, &c.: and those that arise upon occasion only of other ideas; as the effects in us of considering, order, happiness, the beauties of poetry, painting, &c. Secondly, into those which are images of something distinct from sensation, or which imply real, independent of existence and truth; which may be subdivided into such as denote the real properties of external objects, and the actions and passions of the mind; and those which are derived immediately from intelligence. By the notices conveyed to the mind through the organs of the body, or its observation of the necessary attendants and concomitants of certain sensations and impressions, it perceives the figure, extension, motion, and other primary qualities of material substances; by contemplating itself, it perceives the properties of spiritual substances, volition, consciousness, memory, &c. To all these ideas it is essential that they have real, certain, invariable archetypes, actually existing, to which they are referred, and to which they are conformable. These ideas again become objects or archetypes to the intellectual faculty; from whence arises a new set of ideas, which are the perceptions of this faculty, and represent not the mind's own affections, but necessary truth. Antecedently to these, whatever other ideas we may be furnished with, nothing is understood; whatever seeds or subjects of knowledge may be in the mind, nothing is known.

The system of Mr Locke, with regard to the origin of our ideas, has lately been attacked by Dr Reid and others; and it has been charged as the foundation of universal scepticism. Dr Reid objects to every system which supposes that the mind receives images of things from without by means of the senses, because sensations bear no resemblance to bodies, or any of their qualities. With regard to extension, figure, motion, &c. he says, if they are not ideas of sensation, nor like to any sensation, then the ideal system is a rope of sand, and all the laboured arguments of the sceptical philosophy against a material world, and against the existence of every thing but impressions and ideas, proceed upon a false hypothesis. To this objection it has been replied, that ideas are only in a figurative sense the images of external things; that certain impressions are conveyed to the mind by means of the organs of sense, and their corresponding nerves, between which, and the sensations existing in the mind, there is a real and necessary, though at present an unknown connection; and that the same reasoning would lead him to deny that sounds are produced by bodies striking against one another, because he can perceive no proper resemblance between the cause and the effect.

Dr Reid farther objects to the notion generally received among philosophers, that the images of external objects are conveyed by the organs of sense to the brain, and there perceived by the mind. But from this objection it might be inferred, that the whole system of our senses, nerves, and brain, is of no real use whatever; because it is impossible to say how they act upon the mind, or the mind upon them.

It is also objected, that Mr Locke's division of ideas into those of sensation, and those of reflection, is contrary to all the rules of logic; because the second member of the division includes the first. For can we,

says he, form clear and just notions of our sensations any other way than by reflection? Sensation is an operation of the mind, of which we are conscious, and we get the notion of it by reflecting upon that which we are conscious of. In like manner, doubting and believing are operations of the mind, whereof we are conscious, and we get the notion of them by reflecting upon what we are conscious of. The ideas of sensation, therefore, are ideas of reflection, as much as the ideas of doubting or believing, or any other idea whatsoever. But it has been alleged, that the author confounds the ideas of sensation with the idea of sensation itself, which is, without doubt, of the same class with the ideas of doubting, &c. as Mr Locke would have allowed. But the ideas belonging to the class of sensation do not require any scientific knowledge of that power, or any reflection upon it. If this were the case, brute animals, having no proper ideas of reflection, could have no ideas of sensation; and the case would be the same with the bulk of mankind. In another place, Dr Reid acknowledges, that human beings may have ideas of mere sensation some time before they discover any power of reflection, and that this power may discover itself and come into exercise afterwards.

Dr Beattie, Dr Oswald, and others, have pursued and extended the same kind of reasoning against the principles of Mr Locke; and alleged, that Berkeley's reasoning against the existence of a material world, and Hume's reasoning against the existence both of soul and body, are deduced from Locke's Essay, and the Principia of Des Cartes.

In opposition to this system, Dr Reid, and those who have adopted his theory, have recurred to certain instinctive principles; alleging that our perceptions necessarily imply the belief of the present existence of external objects; and that the real, separate, and independent existence of matter, is believed, not because it can be proved by argument, but because the constitution of our nature is such, and we must believe it; and that we cannot, in our own minds, separate the belief of external objects from our sensations. However, it has been urged by an ingenious writer, that Mr Locke's doctrine is not so favourable to Mr Berkeley's theory as Dr Reid's; and that a system which ascribes our primary mental operations to mere constitution and feeling, is more favourable to scepticism than that in the room of which it is substituted. According to Mr Hume's system, all perceptions are either impressions or ideas, and it is not possible for us so much as to conceive any thing specifically different from ideas and impressions; and since all ideas are copied from impressions, we can, therefore, have no idea or conception of any thing of which we have not received an impression. No man can have any idea of power or energy, because he has never received any impression of it; and for the same reason no man can have any idea of self. What we call a mind is nothing but a bundle or collection of different perceptions, which succeed each other with inconceivable rapidity, and are in a perpetual flux and movement. There is properly, says Mr Hume, no simplicity in the mind at one time, nor identity at different times, whatever natural propensity we may have to imagine that simplicity and identity. They are the successive perceptions only that constitute the mind: so that

there

there is nothing in the universe but impressions and ideas; all possible perceptions being comprehended in those two classes. Consequently, this philosophy, excluding body and mind, admits of no existence whatsoever, not even of a percipient being to be the subject of these perceptions. To the same purpose Dr Reid observes, that, according to Mr Locke's system, ideas being the only objects of thought, and having no existence but when we are conscious of them, it necessarily follows, that there is no object of our thought which can have a continued and permanent existence. Body and spirit, cause and effect, time and space, to which we were wont to ascribe an existence independent of our thought, are all turned out of existence by this short dilemma. Either these things are ideas of sensation or reflection, or they are not: if they are ideas of sensation or reflection, they can have no existence but when we are conscious of them: if they are not ideas of sensation or reflection, they are words without any meaning. To which we shall only reply, that we have the same reason to believe, that mind exists as that body exists; since it is only by that name that we distinguish the subject of certain powers or properties, of which we are conscious, as perception, memory, will, &c. and we have just the same reason to believe the identity of an idea as that of any external body, or that of our own minds.

Those who wish to be farther acquainted with the controversy relating to the nature and origin of our ideas, must be referred to Hume's Treatise of Human Nature, vol. i. p. 123, &c. 282, &c. 434, &c. Reid's Inquiry into the Human Mind, passim. Beattie's Essay on Truth, part ii. chap. 2. Priestley's Examination of Reid, Beattie, &c. passim.

INEBRIANTS, are defined to be such things as affect the nerves in a particular and agreeable manner, and through them alter and disturb the functions of the mind. They are properly divided into native and artificial; the former chiefly in use among the oriental and other nations, the latter principally throughout Europe.

Natural Inebriants are, 1. Opium; in use all over the east, and of which the Turks, through custom, swallow a drachm. 2. Peganum harmala, Syrian rue. The seeds are sold in Turkey for this purpose; and with these, as Bellonius relates, the Turkish emperor Solymán kept himself intoxicated. 3. Mastic of the Turks, or bangle of the Persians; prepared from the dust of the male-flower of hemp, or from the leaves. 4. Bangle of the Indians, from the leaves of the hibiscus sabdariffa. 5. Seeds of various species of the datura, or thorny apple. 6. Pinang, or betel of the Indians. 7. Roots of black henbane. 8. The hyoscyamus physaloides. 9. Berries of the deadly nightshade. 10. Leaves of millfoil, are used by the Dalekarlians to render their beer intoxicating. 11. Tobacco, and several others less material are mentioned; such as clary, saffron, and dandel.

Artificial Inebriants, are fermented liquors from farinaceous feeds; wines, and spirits drawn by distillation. With these is ranked the nectar of the gods, and the anodyne medicine of Homer, commonly called *nepenthe*; and the spells by which Medea and Circe produced their incantations.

INFORMATION. Line penult, for *made*, read *mode*.

INJECTION, or INJECTING, in surgery, the throwing in some liquor or medicine into a vein opened by incision. This practice, and that of transfusion, or the conveying the arterial blood of one man, or other animal, into another, were once greatly practised, but are now laid aside.

The method of injecting is this: A vein is to be opened in the arm with a lancet as in bleeding, and the small pipe of a syringe being introduced at the orifice, the liquor intended to be mixed with the blood; and contained for that purpose in the body of the syringe, is to be forcibly injected, or thrown into the vein upwards, or toward the heart; which done, the orifice is to be secured with compresses and bandage, as in bleeding.

The bold experiment of injecting medicated liquors into the human veins was first made in the hospital at Dantzick. One of the patients was a lusty robust soldier dangerously infected with the venereal disease, so that he had exostoses on the bones of his arms. While the liquor, (two drachms of a laxative medicine,) was passing into the vein of his arms, he complained of great pain in his elbows, and the valves of the vein swelled so visibly, that it was necessary to stroke them up with a finger towards the patient's shoulders. In four hours after, it began to operate by stool, and continued to do so till next day; so that the patient had in all five stools from it. The disease disappeared without any other remedy.

A married woman of 35 years of age, and a young woman of 20, had both been so grievously afflicted with epileptic fits from their infancy, that little or no hope could be entertained of their cure. Both of them underwent this singular treatment: into their veins were injected a laxative rosin dissolved in an antiepileptical spirit; but what the rosin and spirit were, we are not told. The married woman had several gentle stools some hours after the injection, and also next day; soon after which the disease vanished; the young woman, it is said, *cast herself away* by going into the air, catching cold, and not observing any diet. It was remarked that all the three patients vomited frequently and severely soon after the injection.

Whether this practice of injecting proper medicines into the blood may not be found of use in apoplexies, quinies, hydrophobia, &c. is worthy to be tried by repeated experiments. The method of injecting liquors into the blood of living animals is said to be the invention of Sir Christopher Wren. His method was by making ligatures on the veins, and opening them on the side of the ligature towards the heart; then putting into them small syringes or quills fastened to bladders, in the manner of clyster-pipes, containing the matter to be injected. Mr Boyle soon made the experiment upon dogs with infusions of opium and crocus metallorum; all which he circumstantially described in his *Usefulness of Experimental Philosophy*, part ii. *ess.* 2.

The ingenious Dr Hales made a variety of experiments of this kind on different animals.

Many disorders of particular parts are now curable, unless the parts affected are injected with a proper liquor, by means of a syringe and proper tube. The method of performing this is too obvious to need any directions; but these general cautions are necessary.

Injection

||
Keratophy-
tum.

fary in regard to it, that the syringe or tube be applied tenderly and carefully to the parts, especially in very sensible or nervous parts, to avoid giving the patient any pain; and that the liquor to be injected be neither too hot nor too cold.

In ulcerations and inflammations of the uvula, tonsils, and fauces, injections are generally useful; but care must be taken to press down the tongue with a spatula, or with the flat end of a spoon; and having introduced the syringe two or three fingers breadth into the mouth, the injection is to be carefully and gently thrown in at several times. In gonorrhoeas, injections are often necessary, to allay the heat and soreness of the urethra, and to wash out the matter. The safest and best injections on this occasion are warm milk and barley-water, sweetened with sugar, honey, or syrup of marshmallows; and towards the end a little saccharum saturni, dissolved in plantane-water.

SYMPATHETIC INKS. Line 8. for *invisible*, read *visible*.

INSECTS. (*Encycl.*) See also **GENERATION of Insects**, and **ENTOMOLOGY**, in this **APPENDIX**.

ISSUE, in law, is the fourth part or stage of an action, (see **SUIT**, **WRIT**, **PROCESS**, and **PLEADINGS**); wherein the parties join, and put their cause to the trial of the jury.

Issues are of two kinds; that upon matter of *fact*,

and that upon matter of *law*. An issue in fact is when the plaintiff and defendant have agreed upon a point to be tried by a jury; an issue in law is when there is a demurrer to a declaration, plea, &c. and a joinder in demurrer, which is an issue at law to be determined by the judges.

Issues in fact are either *general* or *special*.

Issue general, seems to be that whereby it is referred to the jury to bring in their verdict, whether or no the defendant hath done any thing as the plaintiff lays to his charge. For example, if it be an offence against any statute, and the defendant plead not guilty; this being put to the jury, is called the *general issue*. So if a man complains of a private wrong, which the defendant denies, and pleads no wrong, nor disseisin, and this be referred to the jury; it is likewise the general issue.

Issue special, is that, wherein special matters being alleged by the defendant in his defence, both parties join in this point, and so go to a demurrer, if it be *questio facti*; as in assault and battery, where the defendant pleads that the plaintiff struck first.

JUNCI LAPIDÆ, in natural history, the name given by authors to a piece of fossil coral, of the *tubularia* kind, and composed of a congeries of small tubules, which are usually round and striated within. See **PLATE CCCXVII**.

K.

KALMIA, (*Encycl.*) The two species are the latifolia and the angustifolia. The first, a most beautiful shrub, rises usually to the height of five or six feet, and sometimes twice that height in its native places. The stems of some are as big as the small of a man's leg, though generally they are smaller, and covered with a brown rough bark. The wood is very close grained, heavy, and hard like box. The limbs in general are crooked, and grow irregular; but are thick-clothed with stiff smooth leaves of a shining bright green. The flowers grow in bunches on the tops of the branches, to footstalks of three inches long: they are white, stained with purplish red, consisting of one leaf in form of a cup divided at the verge into five sections: in the middle is a stylus and 12 stamina; which, when the flower first opens, appear lying close to the sides of the cup at equal distances, their apices being lodged in ten little hollow cells, which being prominent on the outside, appear as so many little tubercles. The flowers are succeeded by small round capsules; which when ripe open in five parts, and discharge its small dust like seeds. This plant is a native of Carolina, Virginia, and other parts of the northern continent of America; yet are not common, but are found only in particular places: they grow on rocks hanging over rivulets and running streams, and on the sides of barren hills. They blossom in May, and continue in flower the greatest part of the summer. The noxious qualities of this elegant plant lessen that esteem which its beauty claims: for although deer feed on its green leaves with impunity, yet when cattle and sheep, by severe winters deprived of better food, feed on the leaves of these plants, a great many of them die annually.

The *kalmia angustifolia*, rises to the height of about 16 feet, producing evergreen leaves in shape like the *lauro-cerasus*, but small, and of a shining dark green. The flowers grow in clusters, the buds of which appear in autumn wrapped up in a conic scaly perianthium, on which is lodged a viscous matter, which protects them from the severe cold in winter. These buds dilating in the following spring, break forth into twenty or more monopetalous flowers divided into five segments, and set singly on pedicles half an inch long. These flowers, when blown, appear white; but on a near view are of a faint blush colour, which as the flower decays grow paler. One of the five petals is longer and more concave than the rest, and is blended with purple, green, and yellow specks, being a viscous matter on the extremities of very fine hairs. The convex side of the same petal is also speckled with yellowish green. The point rises from the centre of the flower, and has its head adorned with scarlet, and surrounded by 10 stamens, whereof three are long and seven short, whose farina issues out at a small round hole at its top. This elegant tree adorns the western and remote parts of Pennsylvania, always growing in the most sterile soil, or on the rocky declivities of hills and river-banks, in shady moist places.

KERATOPHYTUM, in natural history, a species of **GORGONIA**.—The *keratophyta* are called the *frutices caralloides*, or sea-shrubs; and generally known among naturalists by the different appellations of *litophyta*, *liothoxyla*, and *keratophyta*; epithets tending to convey an idea of their composition, which at first view, seems to consist partly of a woody or horny, partly of a stony or calcareous, substance, variously disposed with

tc-

tophy' respect to each other. Their general form approaches to that of shrubs, having a root-like base, by which they adhere to some solid support in the ocean; and a stem, or trunk, and branches differently disposed; some rising up in one or more different twigs, subdivided into smaller and separate ramifications; while others have their smaller branches connected in such a manner, as to form a curious net-like structure: from this diversity of figure, they borrow the names of *sea-fans*, *sea-feathers*, &c. The seeming fibres of the base are, in reality, small tubes, of which the whole shrub consists: these tubes run up longitudinally into the trunk, and are also circularly disposed about the centre of the trunk: the woody part, as naturalists have called it, thus formed, affords, when burnt, a strong smell like burning horn; whence some have called it *the horny part*. Upon this part is superinduced a kind of stony or calcareous coat, which covers both trunk and branches to their extremities. In this coat may be discovered regular orders or pores of cells; and viewed by the microscope, it always appears to be an organical body consisting of a regular congeries, like the cells in which animals have been formed or existed. Some of this kind of bodies have lost their calcareous covering by the violence of the waves and other accidents. In some specimens of an advanced growth, the calcareous tubes just mentioned, find out little cells of animals of the polype kind, with proper openings to them all: these cells are diffused along the branches in some regular order, much in the same manner as they are in the corallines. From the cells the animals have been discovered extending themselves, as well to procure food as materials for the increase of this surprising structure: and therefore there is no reason to doubt that they are animal productions.

A small sprig of the keratophyton stelliforme, or warted sea-fan, is represented in Plate CCCXVI. fig. 7. c. The outside is covered with a crust full of little lumps like warts; which, when dissolved in vinegar, discover the contracted bodies of polypes, like claws. C and C1 are two views of one of the warts magnified; C2, is the appearance of the polype when the calcareous matter is dissolved; C3, represents the particles that compose the incrustation, magnified.—D, fig. 8. represents a sea-willow, or keratophyton dichotomum. On both edges of the flat branches are regular rows of little rising cells in the calcareous

part, with small holes for an entrance to each. See CORALLINES.

St KILDA, p. 4033. col. 1. line 8. For *having*, read *hanging*.

KINGSTON upon HULL, a town in the East Riding of Yorkshire, seated on the north side of the river Humber. It is a handsome large place with two parish-churches. It is very well fortified, is one of the principal places in England for trade; a county of itself; sends two members to parliament, and has the title of a duchy. W. Long. c. 6. N. Lat. 53. 45.

KIRK-SESSIONS, the name of a petty ecclesiastical judicatory in Scotland. Each parish, according to its extent, is divided into several particular districts; every one of which has its own elder and deacon to oversee it. A consistory of the ministers, elders, and deacons of a parish form a kirk-session.

These meet once a week, the minister being their moderator, but without a negative voice. It regulates matters relating to public worship, elections, catechising, visitations, &c. It judges in matters of less scandal; but greater, as adultery, are left to the presbytery; and in all cases an appeal lies from it to the presbytery.

KNOT, is the name of a punishment inflicted in Russia, with a kind of whip called *knot*, and made of a long strap of leather prepared for this purpose. With this whip the executioners dexterously carry off a slip of skin from the neck to the bottom of the back laid bare to the waist, and repeating their blows, in a little while rend away all the skin off the back in parallel strips. In the common knot, the criminal receives the lashes suspended on the back of one of the executioners: but in the great knot, which is generally used on the same occasions as racking on the wheel in France, the criminal is raised into the air by means of a pulley fixed to the gallows, and a cord fastened to the two wrists tied together; a piece of wood is placed between his two legs, also tied together; and another of a crucial form under his breast. Sometimes his hands are tied behind over his back, and when he is pulled up in this position, his shoulders are dislocated. The executioners can make this punishment more or less cruel: and, it is said, are so dexterous, that when a criminal is condemned to die, they can make him expire at pleasure, either by one or several lashes.

L.

LAMPYRIS, the FIRE-FLY, a genus of insects belonging to the coleoptera order; the characters of which are: The antennæ are filiform; the elytra are flexible; the thorax is flat, of a semiobicular form, surrounding and concealing the head. The segments of the abdomen terminate in papillæ, which are turned up towards the elytra, and partly fold one over the other. The females in general are apterous.

There are 18 species; of which the most remarkable is the noctiluca. The male of this insect is less than the female: its head is shaped exactly in the same manner, and covered likewise by the plate of the thorax, only it appears rather longer than that of the female. Both the head and antennæ are black. The thorax of the male, which is smaller and shorter than that of the female,

has the folds and papillæ on its sides much less remarkable: but the greatest difference that is found between the two sexes is, that the male is covered with brown elytra, shagreened and marked with two lines longitudinally. The elytra are longer than the abdomen, and under them lie the wings. The two last rings of the abdomen are not so bright as those of the female, only there appear four luminous points, two upon each of the two last rings.

The insect called *glow-worm*, and which is frequently met with towards evening, in the month of June, in woods and meadows, is the female belonging to this species. By the shining light which it emits, it attracts the male; a wonderful instance of the divine providence. It is apparent that their shining light depends

Kilda
Lampyrus.

Barbut on
Insects.

depends on a liquor placed at the lower extremity of the insect, which when in motion, the light is more lively and shining, and of a finer green. This light the insect withdraws at pleasure, either by unfolding or contracting itself. As a proof that the light depends on a phosphorous matter, you may crush the animal, which, though dead and bruised, leaves a luminous substance on the hand, that only loses its lustre when dried.

The perfect insect flies about during the evening in autumn, and frequents the grassy plantations of juniper trees.

Beauty of LANGUAGE, p. 4095. col. 2. l. 4. from bottom, for *Part II.* read *Part III.*

LARVA, in natural history, a name given by Linnaeus to insects in that state called by other writers *cruca* or *caterpillar*.

LARVÆ, in antiquity, derived from the Hætruscan word *lar* or *larr*, signifying *prince* or *lord*; denoted the ghosts of the deceased, considered as wicked and mischievous. Hence is formed the term *larvatus*, i. e. *larvâ indutus*, or *demoniac*. The ingenious Mr Farmer urges the etymology and use of this term to prove, that the heathen demons were human ghosts.

LEASE, from the French *laiser*, *demiſſer*, “to lett,” in law, a demise, or letting of lands, tenements, or hereditaments, unto another for life, term of years, or at will, for a rent reserved.

A lease is either written, called an *indenture*, *deed-poll*, or *lease* in writing; or by word of mouth, called *lease parole*.

All estates, interests of freehold, or terms for years in lands, &c. not put in writing and signed by the parties, shall have no greater effect than as estates at will; unless it be of leases not exceeding three years from the making; wherein the rent reserved shall be two-thirds of the value of the things demised. Leases exceeding three years must be made in writing; and if the substance of a lease be put in writing, and signed by the parties, though it be not sealed, it shall have the effect of a lease for years, &c.

An *assignment* differs from a lease only in this; that by a lease one grants an interest less than his own, reserving to himself a reversion; in assignments he parts with the whole property, and the assignee stands to all intents and purposes in the place of the assignor.

LEASE, in Scots law. See **TACK**, (*Encycl.*)

LEPAS, the acorn, in zoology, a genus belonging to the order of vermes testacea. The animal is the triton; and the shell is multivalve, unequal, fixed by a stem or sessile. There are several species, of which the most remarkable is the anatifera, consisting of five shells depressed, affixed to a pedicle and in clusters. It adheres to the bottom of ships by its pedicles. The tentacula from its animal are feathered; and have given the old English historians and naturalists the idea of a bird. They ascribed the origin of the barnacle goose to those shells. See **PLATE CLIX.** fig. 8.

LEUCOMA, in medicine and surgery. See **ALBUGO** in this **APPENDIX**.

LIBELLULA, (*Encycl.*) See **PLATE CCCXXII.**

LIBERTY, p. 4206. col. 2. line 5. from the bottom, for **PARLIAMENT** read **PRÆROGATIVE**.

LIBERTY, physical, is that principle of spontaneity or self-determination which constitutes us agents;

or which gives us a command over our actions, rendering them properly ours, and not effects of the operation of any foreign cause. See **METAPHYSICS**, (*Encycl.*) n^o 78—80. Without this liberty, or being under a necessity of always following some will different from his own, man would be a machine acted upon by mechanical springs, having no principle of motion in himself, or command over events; and therefore incapable of all merit or demerit.

Whether man is endued with this kind of liberty or self-determining power, has been a subject of much controversy: it was agitated at the beginning of this century between Leibnitz, Collins, &c. on one side, and Clarke, Jackson, &c. on the other; and has been lately revived by Dr Priestley.

The principal arguments in favour of liberty, as it is popularly understood, and as it is defined above, are the following. This principle is necessary to constitute man an agent. For, as far as it is true of a being that he acts, so far he must himself be the cause of the action, and therefore not necessarily determined to act: but if he has no absolute power over his own actions, i. e. if he be not a free agent, the actions which he performs cannot properly be said to be his own, but must be ascribed to some other power by which he is led on to perform them; as a good clock or watch performs the motions assigned to it by the artist. This argument is excellently illustrated by Dr Clarke. Man, says he, either has within himself a principle of action; properly speaking, i. e. a self-moving faculty, a principle or power of beginning motion; or he has not. If he has within himself such a principle, then he is a free, and not a necessary agent: for every necessary agent is moved necessarily by something else; and then that which moves it, not the thing itself which is moved, is the true and only cause of the action. That any other thing operating upon an agent should efficiently and necessarily produce self-motion in that agent, is a direct contradiction in terms. If man has not within himself a principle or power of self-motion, then every motion and action of man is chiefly and properly produced by the efficiency of some extrinsic cause; which cause must be either what we usually call the motive or reason upon which a man acts; or else it must be some insensible subtle matter, or some other being or substance making an impression upon him. If the reasons or motives upon which a man acts be the immediate and efficient cause of the action, then either abstract notions, such as all reasons and motives are, have a real subsistence, that is, are themselves substances; or else that which has itself no real subsistence can put a body into motion; either of which is manifestly absurd. If insensible subtle matter, or any other being or substance, continually making impression upon a man, be the immediate and efficient cause of his acting; then the motion of that subtle matter or substance must be caused by some other substance, and the motion of that by some other, till at last we arrive at a free agent; and then liberty is a possible thing, and man possibly may have liberty: and if he may possibly have it, then experience will prove that he probably, nay, that he certainly has it. If we never arrive at any free cause, then there is either *in infinitum* a progression of motions without any mover, of effects with-

without any cause, of things acted without any agent; which is a manifest contradiction, or else motion exists necessarily of itself. If motion exists necessarily of itself, it must be either with a determination every way, or one certain way: if with a determination every way, this is no motion at all; if with a determination one certain way, then that determination is either necessary, and consequently all other determinations impossible, which is contrary to experience; or else there must be a particular reason of that determination, and so backwards in *infinitum*; which comes to the fore-mentioned absurdity, of effects existing without any cause.

Farther, liberty is the dictate of our own consciousness: we have really the same constant and necessary consciousness of liberty that we have that we think, choose, will, or even exist; and, whatever men may say to the contrary, it is impossible for them in earnest to think they have no active self-moving powers, and are not the causes of their own volitions, or not to ascribe to themselves what they must be conscious they think and do. Mr Hume, though he denies the reality of liberty, grants that we have a feeling of it; that the divine plan required that we should be so made, as to seem to ourselves free; that the whole constitution of things is as if we were free; and that being under a necessity of approving and disapproving actions and characters, we are so far under a necessity of believing ourselves and others free. After these concessions, it can hardly be imagined that the constitution of nature should be altogether imposition and deceit.

Besides, if man be not, in the strictest sense of the word, a free agent, he can be no moral agent. It is hard to say what virtue and vice, commendation and blame, mean, if they do not suppose agency, voluntary motion, free choice, and an absolute dominion over our resolutions. Can we applaud or reproach ourselves for what we were no more the causes of than of our own beings, and what it was no more possible for us to prevent than the returns of the seasons, or the revolutions of the planets? On the system of necessity, conscience is an inexcusable principle: its censures or applause are equally futile and groundless: the approbation of mankind is an insult with regard to those on whom it is bestowed, because they can have no merit; and the reproach of men unjust and cruel, because there can be no demerit and ground of blame. Whatever difficulties, therefore, may attend the nature of that influence which we ascribe to motives, they cannot be the efficient necessitating cause of human actions: since, on this supposition, there could be but one agent in the universe; who must equally be the author of all the good and evil in the world, and on whom must ultimately be charged the sin and misery, as well as the virtue and happiness, of his creatures.

Moreover, it has been urged by the advocates of liberty, that if mens determinations and actions flow necessarily from the previous state of their minds and the motives or influences resulting from a nature or condition imposed upon them without their own consent or choice, the idea of responsibility or accountability must vanish, and there can be no propriety or use of rewards or punishments. God cannot reward without virtue, and there can be no virtue without a self-deter-

mining power: he cannot punish without guilt, and there can be no guilt when men do what they cannot avoid doing, and when their actions arise from circumstances in which their Creator placed them.

It is also equally unjust and useless to threaten punishment or inflict it on men, to prevent crimes, when they are necessarily determined in all their actions. And if men are necessary agents, though we cannot well admit this verbal contradiction, it can be of no use to reason with them, to admonish or treat them; and God must be insincere in his addresses and invitations, and cruel in his requirements and commands. But such is the whole tenor of revelation; and therefore the conclusion is necessary, that man is a free agent, capable of good or evil, and of determining his pursuit of either, from the sole power of his own judgment or will. See on this subject Collins's Inquiry concerning Human Liberty, first printed in 1717. Clarke's Remarks, 1717; and Collection of Papers which passed between Mr Leibnitz and Dr Clarke, in 1715 and 1716. Jackson's Vindication and Defence of Human Liberty, 1730. Price's Review of the principal Questions, &c. in Morals, p. 315, &c. edit. 1758. Priestley's Doctrine of Philosophical Necessity, 1777.—For the objections against liberty, and the arguments in support of necessity, see NECESSITY.

LIEUTAUD (Dr Joseph), counsellor of state and first physician at the court of France, was born at Aix in Provence, and resided principally there till he took the degree of doctor of medicine. After this he prosecuted his studies for some years at Montpellier. He returned to Aix, where he soon acquired extensive practice, and became eminent for literary abilities. He resided there till the year 1750, when he was invited to act as physician to the royal infirmary at Versailles. There he practised with such reputation and success, that he soon arrived at the head of his profession; and in the year 1774, upon the death of M. Senac, he was appointed archibier. His extensive engagements in practice did not prevent him from cultivating the science of medicine in all its branches, and from freely communicating to others the result of his own studies. He published many valuable works; among which the following may be accounted the most remarkable, 1. *Elementa Philologie*. 2. *Precis de la Medicine*. 3. *Pratique Precis de la Matiere Medicale*. 4. *Essai Anatomique*. 5. *Synopsis Universae Praxeos Medicinæ*. 6. *Historia Anatomico-Medicæ*. He died at Versailles Dec. 8. 1780. in the 78th year of his age.

LINARIA, TOAD-FLAX, in botany. See ANTIRRHINUM, (*Encecl.*)

LIPOTHYMIA, Fainting; in medicine. See there, n° 207, 382, 383.

LITHOSTROTION, in natural history, the name of a species of fossil coral, composed of a great number of long and slender columns, sometimes round, sometimes angular, joined nicely to one another, and of a starry or radiated surface at their tops. These are found in considerable quantities in the northern and western parts of this kingdom, sometimes in single, sometimes in complex specimens. See Plate CCCXVII.

LUNARIA, MOON-WORT, in botany. See OS-MUNDA in this APPENDIX.

LYMINGTON, a town of Hampshire in England situated on a hill near the sea, in W. Long. 1.

Macbride. 45. N. Lat. 50. 45. It sends two members to parliament, and is remarkable for the great quantities of sea-salt made in the neighbourhood. At these salt-works are prepared great quantities of sal catharticus amarus, which being shot into large crystals is sold for true Glauber's salt, under the name of *Ly-mington's salts*.

LYCANTHROPIA, a terrible kind of madness; Lycanthro-
supposed to be that which in Scripture is called pos-
session with a legion of devils. See MEDICINE, Pis,
II
n° 86. Macbride.

LYCOPERSICON, in botany; *love apple, wolf's peach, or tomato*. See SOLANUM, (*Encycl.*)

M.

MACBRIDE (Dr David), an eminent physician and philosopher, was descended from an ancient family in the county of Galloway in Scotland. His grandfather, a clergyman, had settled in Ireland about the end of the last century, as minister to a Presbyterian congregation at Belfast; and his father, who followed the same line, was settled at Ballymony in the county of Antrim, where he married, and where our author was born in April 1726. After a proper school-education, and having passed some time under the tuition of an eminent surgeon in his native place, he was sent to the university of Glasgow. Having there completed the usual course of academical studies, he came to Edinburgh for the further prosecution of medical science. After a short stay here, a war then prevailing between France and Britain, he was induced to go on board the navy in the station of a surgeon's mate. In the service of his country he continued for several years; and after discharging for some time the duties of an assistant, he was raised to the rank of surgeon. In this situation, he first turned his thoughts towards the discovery of a remedy for the sea-scurvy. It was not, however, at this period, that either chance or reasoning suggested to him the employment of an article, which has since been attended with the most beneficial consequences. Here he had an opportunity only of observing the symptoms, of studying the nature, and of lamenting the consequences of the disease.

The termination of the war by the peace of Aix-la-Chapelle, put a period to Dr Macbride's employment as a naval surgeon. He had now probably obtained much medical knowledge in the school of experience; but he was sensible that he had still much to acquire in that of science. An ardent keanness to mingle in active life had led him from the schools of medicine at an earlier period than could have been wished; and an earnest desire to found his future practice in the best established principles led him back to them, when a judgment, matured by years, and informed from the observation of facts, rendered him capable of hearing teachers with greater advantage. He returned therefore to Edinburgh, and again entered on the career of academical pursuits, under the tuition of Dr Monro, and those other teachers, whose abilities raised the fame of the medical school at this place. But, not satisfied with the instructions to be had from any one set of professors, the celebrity of the medical teachers in London led him also to visit that capital. There he particularly became the pupil of those distinguished lecturers, Dr Hunter and Dr Smellie. And while from the former he laboured to acquire an accurate surgical knowledge, from the latter he endeavoured to obtain the true principles of midwifery considered as a science. At the same time, he was no less in-

dustrious in improving himself in the successful practice of both arts by attention at hospitals.

Thus prepared for the exercise of his profession, about the end of the year 1749 he fixed his residence in Dublin in the character of surgeon and accoucheur. If amiable manners, and extensive knowledge of his profession, could alone have been sufficient introductions to practice, he might in a short time have looked for a competent share of business in that capital; but while he had to combat that objection which very generally arises from youth, his progress was also not a little retarded by an uncommon degree of modesty. Hence for several years he remained almost in a state of obscurity, and was employed by but few people either of rank or fortune. But, if it is to be regretted that for many years his time was not so fully employed in the lucrative part of his profession as was due to his merit, it ought still to be remembered, that this essentially promoted the cause of science: for by this means his genius and industry were directed to medical researches; and were productive of discoveries which will with honour transmit his name to late posterity. These, though some of them might have been successfully turned to his own emolument, were fully communicated to the world in different publications; and he did not show greater ingenuity in making discoveries, than liberality of sentiment in publishing them for the advantage of others.—His first publication, intitled, "Experimental Essays on medical and philosophical Subjects," made its appearance in the year 1764.—These essays are five in number: 1. On the fermentation of alimentary mixture and the digestion of the food. 2. On the nature and properties of fixed air. 3. On the different kinds of antiseptics. 4. Of the dissolvent power of quicklime. 5. Of the sea-scurvy. The merit of all these is sufficiently known and acknowledged: but the last of them is unquestionably the most important; the method therein proposed of both the prevention and cure of that dreadful disease the scurvy, having been confirmed by repeated and undeniable observation.

Having thus equally distinguished himself as an ingenious philosopher and able practitioner, the world were not now slow in bestowing upon him the tribute of applause to which he was entitled. His name was enrolled with honour in the lists of many learned societies; and the university where his studies had first been commenced, were proud to confer upon him the degree of Doctor of Medicine.

The reputation, however, of being a distinguished author, was to him but a secondary object; and his talents were not confined to the advancement of medicine alone. Having successfully discovered a considerable improvement in the art of tanning, with that spirited generosity which is ever the concomitant of real

Macbride, real worth, he speedily and freely communicated it to the public, by publishing, first, "An account of a new method of tanning;" and afterwards, "Instructions for carrying on the new method of tanning." As a mark of approbation for this liberal conduct, as well as a testimony of respect for his ingenuity, prize-medals were conferred upon him by the Societies of Arts both in London and Dublin. But his last and most extensive publication was more immediately in the line of his own profession: It is intitled, "A Methodical Introduction to the Theory and Practice of Medicine." In that valuable work he has given a concise and connected view of the principles and practice of the healing art, as best established by sound reasoning, and confirmed by accurate observation. Most, if not all these publications, not only went thro' various editions, but were translated into different languages.

After the merit of Dr Macbride came to be properly known, the public seemed to show a desire of making compensation for having so long overlooked it. His employment increased so rapidly, that he had more business than he could transact either with ease or safety. This having kept him in perpetual agitation both of body and mind, at last induced an almost total incapacity of sleeping. From this circumstance his health could not fail to be impaired. In this situation, after accidental exposure to cold, he was attacked with a fever, which put an end to his life on the 13th of December 1778, in the 53d year of his age.

Those who were his most intimate acquaintance were inclined to believe that his death was not a little hastened by domestic calamities. During his residence in Dublin he was twice married, and was as often subjected to that inexpressible distress which must result from a final separation in this world from the most intimate and loving friends. By both of his wives he had several children; but none of them survived their father. And on these calamitous events, although he was able to conceal his feelings from the world, yet they gave a severe shock to his constitution. After his death, several of the playful trinkets of his infants, with the signature of *dulces exuvia*, were found in his repositories among papers on medical and other important subjects: an incontrovertible proof, that in him at least, the great mind of the philosopher was conjoined with the feeling heart of the affectionate father.

But if his abilities were remarkable as a philosopher and physician, if his conduct was exemplary as an husband and parent, his manners were no less amiable as a companion and friend. His polite and benevolent conduct, joined to his taste for the fine arts, conciliated the affections and esteem of all who knew him. His death was universally and sincerely lamented in the city of Dublin.

MADREPORA, in natural history, the name of a genus of submarine substances; the characters of which are, That they are almost of a stony hardness, resembling the corals, and are usually divided into branches, and pervious by many holes or cavities, which are frequently of a stellar figure.

In the Linnean system, this is a genus of lithophyta: The animal that inhabits it is the medusa; it comprehends 39 species. According to Donati, the madrepora is like the coral as to its hardness, which is equal to bone or marble; the colour is white

when polished; its surface is lightly wrinkled, and the wrinkles run lengthwise of the branches; in the centre there is a sort of cylinder, which is often pierced thro' its whole length by two or three holes. From this cylinder are detached about 17 laminae, which run to the circumference in straight lines; and are transversely intersected by other laminae, forming many irregular cavities; the cellules, which are composed of these laminae ranged into a circle, are the habitations of little polypes, which are extremely tender animals, generally transparent, and variegated with beautiful colours. M. de Peyssonel observes, that those writers who only considered the figures of submarine substances, denominated that class of them, which seemed pierced with holes, *pora*; and those, the holes of which were large, they called *madrepore*. He defines them to be all those marine bodies which are of a stony substance, without either bark or crust, and which have but one apparent opening at each extremity, furnished with rays that proceed from the centre to the circumference. He observes that the body of the animal of the madrepora, whose flesh is so soft that it divides upon the gentlest touch, fills the centre; the head is placed in the middle, and surrounded by several feet or claws, which fill the intervals of the partitions observed in this substance, and are at pleasure brought to its head, and are furnished with yellow papillae. He discovered that its head or centre was lifted up occasionally above the surface, and often contracted and dilated itself like the pupil of the eye: he saw all its claws moved, as well as its head or centre. When the animals of the madrepora are destroyed, its extremities become white. In the madrepora, he says, the animal occupies the extremity; and the substance is of a stony but more loose texture than the coral. This is formed, like other substances of the same nature, of a liquor which the animal discharges; and he farther adds, that there are some species of the polype of the madrepora, which are produced singly, and others in clusters.

MALALEUCA, the *CAYPUTI* TREE; a genus of the polyandria order, belonging to the polyadelphia class of plants. There is but one species, viz. the leucodendra, a native of the East Indies and South-Sea islands. Mr Forster relates that they were found in the island of New Caledonia. They were black at the root, but had a bark perfectly white and loose, with long narrow leaves like our willows. The leaves are extremely fragrant and aromatic; and Rumphius tells us, that from them the natives of the Moluccas make the oil called *cayputi*. This oil is commended as a nervous medicine, and as being useful in some cardialgies. The dose is four or five drops in some convenient liquor.

MAGNOLIA, (*Encycl.*) The glauca generally grows in a poor swampy soil, or on wet meadows. The English and Swedes in Pennsylvania and New Jersey call it *beaver-tree*, because the root of this tree is the dainty of beavers, which are caught by its means. It drops its leaves early in autumn, though some of the young trees kept them all the winter. This tree is seldom found to the north of Pennsylvania, where it begins to flower about the end of May. The scent of its blossoms is exquisite: for by it you can discover, within three quarters of an English mile, whether these little trees stand in the neighbourhood, provided

the wind be not against it; for the whole air is filled with this sweet and pleasant odour. It is beyond description agreeable to travel in the woods about that time, especially towards night. They retain their flowers for three weeks, and even longer, according to the quality of the soil on which the trees stand; and during the whole time of their being in blossom, they spread their odoriferous exhalations. The berries likewise look very fine when they are ripe; for they have a rich red colour, and hang in bunches on slender stalks. The cough and other pectoral diseases are cured by putting the berries into rum or brandy, of which a draught every morning may be taken: the virtues of this remedy were universally extolled, and even praised, for their salutary effects in consumptions. The bark being put into brandy, or boiled in any other liquor, is said not only to ease pectoral diseases, but likewise to be of some service against all internal pains and heat; and it was thought that a decoction of it could stop the dysentery. Persons who had caught cold boiled the branches of the beaver-tree in water, and drank it of their great relief. *Kalm.*

MAN-OF-WAR BIRD, (*Pelecanus Aquilus*, Lin.) Its bill is more than a hand's-breadth long, and is narrow: the upper jaw is somewhat the longest, with a hook-shaped point: the cere, which is blue, covers the bill from the eyes to the hook-shaped point: the mandibles have no such serrated incisions (supplying the place of teeth) as are usually found in sea-birds: the head is covered with short feathers as far as the eyes, which are pretty large: the tongue is large, almost trifid at the top; the corner at its bottom is split: the temples are naked: the wings consist of three parts, and are very long; of the 22 quill feathers, the first ten are of a considerable length; the two inner joints contain, besides the coverts, 22 secondary feathers: the outward of the 12 tail-feathers are much longer than the middle ones, which make the tail look like a pair of scissars. The bird is about the size of a goose, and is a yard long: the colour of the whole body, and of the toes, is black; but the head, breast, belly, and fore-part of the neck, are of a fine white. Its food is fishes, which it takes from others, because it is not formed to catch them itself: the English for this reason call it *man of war*.

MARANTA, line 4. for *Galanea*, read *Galanga*.

MARELLA, a town of Andalusia in Spain, situated at the mouth of the Rio Verde, 30 miles north-east of Gibraltar, and 28 south-west of Malaga. W. Long. 5. 25. N. Lat. 30. 25.

MARINE REMAINS, a term used by many authors to express the shells of sea-fishes, and parts of crustaceous and other sea-animals, found in digging at great depths in the earth, or on the tops of high mountains. Their being lodged in these places, is an evident and unquestionable proof of the sea's having once been there, since it must have covered those places where it has left its productions. It has been a favourite system with many, and particularly with the late Dr Woodward, that all these marine bodies were brought to the places where they now lie, by the waters of the universal deluge; which, as we are informed by holy writ, covered the whole surface of the globe, and even the highest mountains. But though this is a very ready expedient to account for many of the natural

phenomena, yet there are evident proofs that it cannot have been the cause of all that is attributed to it; and there must necessarily have been some other cause of many of these remains having been placed where we now find them. Neither does the opinion of some particular authors, that partial inundations of different places have left these marine bodies behind them at the reefs of the waters, seem sufficient to account for the multitudes of these remains, many of which we find thrown upon places inaccessible to such floods.

Signior Moro has attempted to account for these phenomena on a new plan of reasoning. He observes, that it is the best basis of argument to begin from facts; and that if we can certainly find how some part of these animal remains come to be deposited at such great distances from their natural residence, we may very rationally conclude, that by the same means, be they what they will, all the rest were also brought thither. He adds, that the earth, once the bottom of the sea, or the level surface of a plain, may be, and frequently has been, in the memory of man, raised up into a mountain by subterranean fires, earthquakes, and volcanoes. He mentions the famous instance of the new island raised out of the bottom of the sea near Santorini in the year 1707, which became of a circumference not less than six miles, and of the new mountain raised near Puzzoli in 1538.

These, and many other like facts, prove that the origin of mountains and islands may have been such, and that the matter they consist of may have been the same with what was once the bottom of the sea; and that the marine bodies found in these mountains were such as were living, or remaining of living fish at the time when the islands or mountains were so raised above the surface of the water which before covered it.

This is no new opinion; but this author has set it in a new and much stronger light than it ever had appeared in before, by the instances and examples he has brought in proof of it. Some have been fond of believing that the bodies we call *marine remains*, were never indeed any parts of living animals, but that they are mere *lusi naturæ* formed in the places where they are found; but Fabius Columna proved this to be an error, showing that the shark's teeth, or glossopetræ of the island of Malta, when calcined by a strong fire, yielded almost the same with those from animal-bodies, and by no means of the same nature with those produced from calcined stones.

That changes of parts of the bottom of the sea into dry land, have often been made, is proved not only from the late known instances, but from the testimonies of Strabo, Pliny, and other writers of credit; and nothing is more obvious to reason, than that in the sudden rise of such parts of the bottom of the sea, all its contents, all the shells, and other hard parts of fishes lying there, would be carried up with it.

As some mountains and some islands must have certainly been produced in this manner, it is not impossible but that all of them may have been so; and there is no more than this required to account clearly and evidently for all the vast profusion of marine bodies at land as we find them, without having recourse to the improbable means of the universal deluge, which for many plain reasons cannot have been the cause; or to the

arita-
jum,
alora.

the effects of particular inundations, which must have been wholly incapable of lodging many of them there. The lodgment of shells in the solid strata of mountains, is better accounted for by this system of Signior Moro than any other: and if it be asked why some mountains afford them in great plenty, and others not at all, it will not be difficult to answer, by observing, that among the mountains of the more known parts of the world, some consist of mere solid rock, and others of various strata of earthy and other matter; that the first of these may be supposed primary or natural mountains, and the others secondary or accidental ones; and that these marine remains are always wanting in the former, and usually are found in the latter, which is a fact greatly favourable to this system.

There are many difficulties attending the accounts of all authors of the formation of the earth, and the lodging these bodies in it; nor is this last system without difficulty. The causes here assigned as to the origin of mountains and islands, doubtless have been so in regard to some, but scarce to all; and the bodies here treated of are so numerous, in some particular places, that scarce any account can solve the difficulty of their being collected together in so strange a manner.

MARITAGIUM, (*Encycl.*) In the feudal customs, *maritagiū* (as contradistinguished from *matrimonium*) signifies the power which the lord or guardian in chivalry had of disposing of his infant ward in matrimony. For while the infant was in ward, the guardian had the power of tendering him or her a suitable match, without disparagement or inequality: which if the infants refused, they forfeited the value of the marriage, *valorem maritaggi*, to their guardian; that is, so much as a jury would assess, or any one would *bona fide* give to the guardian for such an alliance: and if the infants married themselves without the guardian's consent, they forfeited double the value, *duplicem valorem maritaggi*.

MASCULUS FLOS. See *Flos Masculus* in this APPENDIX.

MASORA, a term in the Jewish theology, signifying a work on the Bible, performed by several learned rabbins, to secure it from any alterations which might otherwise happen.

Their work regards merely the letter of the Hebrew text; in which they have, first, fixed the true reading by vowels and accents: they have, secondly, numbered not only the chapters and sections, but the verses, words, and letters of the text: and they find in the Pentateuch 5245 verses, and in the whole Bible 23206. The masora is called, by the Jews, the *bedge or fence of the law*, because this enumeration of the verses, &c. is a means of preserving it from being corrupted and altered. They have, thirdly, marked whatever irregularities occur in any of the letters of the Hebrew text; such as the different size of the letters, their various positions and inversions, &c. and they have been fruitful in finding out reasons for these irregularities and mysteries in them. They are, fourthly, supposed to be the authors of the Keri and Chetibh, or the marginal corrections of the text in our Hebrew Bibles.

The text of the sacred books, it is to be observed, was originally written without any breaks or divisions into chapters or verses, or even into words; so that a whole book, in the ancient manner, was but one continued word; of this kind we have still several ancient

manuscripts, both Greek and Latin. In regard, therefore, the sacred writings had undergone an infinite number of alterations, whence various readings had arisen, and the original was become much mangled and disguised, the Jews had recourse to a canon, which they judged infallible, to fix and ascertain the reading of the Hebrew text; and this rule they call *masora*, "tradition," from מסרה, *tradidit*, as if this critique were nothing but a tradition which they had received from their forefathers. Accordingly they say, that when God gave the law to Moses at mount Sinai, he taught him, first, the true reading of it; and, secondly, its true interpretation; and that both these were handed down by oral tradition, from generation to generation, till at length they were committed to writing. The former of these, viz. the true reading, is the subject of the masora; the latter, or true interpretation, that of the *mishtva* and *gemara*.

According to Elias Levita, they were the Jews of a famous school at Tiberias, about 500 years after Christ, who composed, or at least began, the masora; whence they are called *masorites*, and *masoretic doctors*. Aben Ezra makes them the authors of the points and accents in the Hebrew text, as we now find it; and which serve for vowels.

The age of the masorites has been much disputed. Archbishop Usher places them before Jerom; Capel, at the end of the fifth century; father Morin, in the tenth century. Basnage says, that they were not a society, but a succession of men; and that the masora is the work of many grammarians, who, without associating and communicating their notions, composed this collection of criticisms on the Hebrew text. It is urged that there were masorites from the time of Ezra and the men of the great synagogue, to about the year of Christ 1030; and that Ben Asher and Ben Naphtali, who were the best of the profession, and who, according to Basnage, were the inventors of the masora, flourished at this time. Each of these published a copy of the whole Hebrew text, as correct, says Dr Prideaux, as they could make it. The eastern Jews have followed that of Ben Naphtali, and the western that of Ben Asher; and all that has been done since is to copy after them, without making any more corrections or masoretic criticisms.

The Arabs have done the same thing by their Koran that the masorites have done by the Bible; nor do the Jews deny their having borrowed this expedient from the Arabs, who first put it in practice in the seventh century.

There is a great and little masora printed at Venice and at Basil, with the Hebrew text, in a different character. Buxtorf has written a masoretic commentary, which he calls *Tiberias*.

MASQUE, or **MASK**, a cover for the face, contrived with apertures for the eyes and mouth; originally worn chiefly by women of condition, either to preserve their complexion from the weather, or out of modesty, to prevent their being known.

Poppæa, wife of Nero, is said to be the first inventor of the masque; which she did to guard her complexion from the sun and weather, as being the most delicate woman, with regard to her person, that has been known.

Theatrical masques were in common use both among

Masora,
Masque.

Masquerade the Greeks and Romans: Suidas and Athæneus ascribe the invention of them to the poet Cherilus, a contemporary of Theopis; Horace attributes them to Æschylus; but Aristotle informs us, that the real inventor, and consequently the time of their first introduction and use, were unknown. Brantome observes, that the common use of modern masques was not introduced till towards the end of the 16th century.

MASQUERADE, or **MASCARADE**, an assembly of persons masked or disguised, meeting to dance and divert themselves. This was much in use with us, and has been long a very common practice abroad, especially in carnival time.

The word comes from the Italian *mascarata*, and that from the Arabic *maskara*, which signifies "rallery, buffoonery." Granacci, who died in 1543, is said to have been the first inventor of masquerades.

MEASURES, (*Encycl.*) It is necessary, for the convenience of commerce, that an uniformity should be observed in weights and measures, and regulated by proper standards. A foot-rule may be used as a standard for measures of length, a bushel for measures of capacity, and a pound for weights. There should be only one authentic standard of each kind, formed of the most durable materials, and kept with all possible care. A sufficient number of copies, exactly corresponding to the principal standard, may be distributed for adjusting the weights and measures that are made for common use. There are several standards of this kind both in England and Scotland. See the article **WEIGHTS and MEASURES**, (*Encycl.*)

If any one of the standards above-mentioned be justly preserved, it will serve as a foundation for the others, by which they may be corrected, if inaccurate, or restored, if entirely lost. For instance, if we have a standard foot, we can easily obtain an inch, and can make a box, which shall contain a cubical inch, and may serve as a standard for measures of capacity. If it be known that a pint contains 100 cubical inches, we may make a vessel five inches square, and four inches deep, which will contain a pint. If the standard be required in any other form, we may fill this vessel with water, and regulate another to contain an equal quantity. Standards for weights may be obtained from the same foundation; for if we know how many inches of water it takes to weigh a pound, we have only to measure that quantity, and the weight which balances it may be assumed as the standard of a pound.

Again, if the standard of a pound be given, the measure of an inch may be obtained from it: for we may weigh a cubical inch of water, and pour it into a regular vessel; and having noticed how far it is filled, we may make another vessel of like capacity, in the form of a cube. The side of this vessel may be assumed as the standard for an inch; and standards for a foot, a pint, or a bushel, may be obtained from it. Water is the most proper substance for regulating standards; for all other bodies differ in weight from others of the same kind; whereas it is found by experience that spring and river water, rain, and melted snow, and all other kinds, have the same weight; and this uniformly holds in all countries when the water is pure, alike warm, and free from salt and minerals.

Thus, any one standard is sufficient for restoring all the rest. It may further be desired to hit on some ex-

pedient, if possible, for restoring the standards, in case that all of them should ever fall into disorder, or should be forgotten, through the length of time, and the vicissitudes of human affairs. This seems difficult, as no words can convey a precise idea of a foot-rule, or a pound weight. Measures, assumed from the dimensions of the human body, as a foot, a handbreadth, or a pace, must nearly be the same in all ages, unless the size of the human race undergo some change; and therefore, if we know how many square feet a Roman acre contained, we may form some judgment of the nature of the law which restricted the property of a Roman citizen to seven acres; and this is sufficient to render history intelligible; but it is too inaccurate to regulate measures for commercial purposes. The same may be said of standards, deduced from the measure of a barley-corn, or the weight of a grain of wheat. If the distance of two mountains be accurately measured and recorded, the nature of the measure used will be preferred in a more permanent manner than by any standard; for if ever that measure fall into disuse, and another be substituted in its place, the distance may be measured again, and the proportion of the standards may be ascertained by comparing the new and ancient distances.

But the most accurate and unchangeable manner of establishing standards is, by comparing them with the length of pendulums. The longer a pendulum is, it vibrates the slower; and it must have one precise length in order to vibrate in a second. The slightest difference in length will occasion a difference in the time; which will become abundantly sensible after a number of vibrations, and will be easily observed if the pendulum be applied to regulate the motion of a clock. The length of a pendulum which vibrates seconds in London is about 39½ inches, is constantly the same at the same place; but it varies a little with the latitude of the place, being shorter as the latitude is less. Therefore, though all standards of weights and measures were lost, the length of a second pendulum might be found by repeated trials; and if the pendulum be properly divided, the just measure of an inch will be obtained; and from this all other standards may be restored.

1. *Measures of length.* *Lineal* measure is regulated by the yard. The use of this measure was established by Henry I. of England, and the standard taken from the length of his own arm. It is divided into 36 inches, and each inch is supposed equal to 3 barley-corns. When used for measuring cloth, it is divided into 4 quarters, and each quarter subdivided into 4 nails. The English ell is equal to a yard and a quarter, or 45 inches, and is used in measuring linens imported from Germany and the Low-Countries.

The Scots *elwand* was established by king David I. and divided into 37 inches. The standard is kept in the council chamber of Edinburgh, and being compared with the English yard, is found to measure 37½ inches; and therefore the Scots inch and foot are larger than the English, in the proportion of 180 to 185; but this difference being so inconsiderable, is seldom attended to in practice. The Scots ell, though forbidden by law, is still used for measuring some coarse commodities, and is the foundation of the land-measure of Scotland.

A hand in horsemanship is 4 inches.
 A span 9 inches.
 A geometrical pace 5 feet.
 A fathom, chiefly used in measuring depth, 6 feet.

Itinerary measure is regulated by Table IX. (see ARITHMETIC, p. 655.) both in England and Scotland. The length of the chain is 4 poles, or 22 yards; 80 chains make a mile. The old Scots computed miles were generally about a mile and a half each.

The reel for yarn is $2\frac{1}{2}$ yards, or 10 quarters, in circuit; 120 threads make a cut, 12 cuts make a half or hank, and 4 hanks make a spindle.

2. *Land measure.* This, in England, is regulated by Tab. VII. (see ARITHMETIC, p. 655.) Because the length of a pole is 5 yards and a half, the square of the same contains $30\frac{1}{4}$ square yards. A square mile contains 640 square acres. In measuring fens and woodlands, 18 feet are generally allowed to the pole, and 21 feet in forest-lands.

A hide of land, frequently mentioned in the earlier part of the English history, contained about 100 arable acres; and 5 hides were esteemed a knight's fee. At the time of the Norman conquest, there were 243,600 hides in England.

Scots land-measure is founded on the Scots ell, and regulated by Tab. VIII. (See ARITHMETIC, p. 655.) The proportion between the Scots and English acre, supposing the feet in both measures alike, is as 1369 to 1089, or nearly as 5 to 4. If the difference of the feet be regarded, the proportion is as 10,000 to 7869. The length of the chain for measuring land in Scotland is 24 ells, or 74 feet.

A husband-land contains 6 acres of sock and scythe land, that is, of land that may be tilled with a plough or mown with a scythe: 13 acres of arable land make one ox-gang, and 4 ox-gangs make a pound-land of old extent.

3. *Liquid measure.* The English gallon was originally founded on the Troy weight. It was appointed that 8 lb. Troy of wheat, gathered from the middle of the ear, and well dried, should make a gallon. When averdupois weight came into use, another gallon was formed from it in the same manner; which therefore is greater than the former, in the same proportion that the lb. averdupois exceeds the lb. Troy.

The wine-gallon is now appointed to contain 231 inches; and a cylindrical vessel, 7 inches diameter and 6 inches deep, which answers almost exactly to that capacity, is also appointed to be a legal wine-gallon. This measure is used for wine, spirits, vinegar, oil, cyder, perry, and honey.

The ale-gallon is appointed to contain 282 inches; and is used in selling malt-liquors of all kinds, and in collecting the revenue of excise.

Table of Wine Measures.

| |
|---------------------|
| 2 pints=1 quart |
| 2 quarts=1 pottle |
| 3 pottles=1 gallon |
| 10 gallons=1 anker |
| 18 gallons=1 runlet |
| 3½ gallons=1 barrel |
| 42 gallons=1 tierce |
| 2 bar. or 1 hoghead |
| 63 gallons=1 butt |

Table of Ale Measures.

| |
|-------------------------|
| 2 pints=1 quart |
| 2 quarts=1 pottle |
| 2 pottles=1 gallon |
| 8 gallons=1 firkin ale |
| 9 gallons=1 firkin beer |
| 2 firkins=1 kilderkin |
| 4 firkins=1 barrel |
| 2 barrels=1 hd. |
| 2 hds.=1 butt |

84 gallons=1 puncheon 2 butts=1 ton
 2 hds.=1 pipe or butt
 2 butts=1 ton

The barrel for ale in London is 32 gallons, and the barrel for beer 36 gallons. In all other places of England, the barrel, both for ale and beer, is 36 gallons.

For the Scots measures, see PINT, (Encycl.)

4. *Dry measures.* The standard for measuring corn, salt, coals, and other dry goods, in England, is the Winchester gallon, which contains $272\frac{1}{2}$ cubic inches. The bushel contains 8 gallons, or 2178 inches. A cylindrical vessel, $18\frac{1}{2}$ inches diameter, and 8 inches deep, is appointed to be used as a bushel in levying the malt-tax. A vessel of these dimensions is rather less than the Winchester bushel of 8 gallons, for it contains only 2150 inches; though probably there was no difference intended.

The denominations of dry measure commonly used, are given in Tab. V. (see ARITHMETIC, p. 655.) Four quarters corn make a chaldron, 5 quarters make a wey or load, and 10 quarters make a ton. In measuring sea-coal, 5 pecks make a bushel, 9 bushels make a quarter or vatt, 4 quarters make a chaldron, and 21 chaldrons make a score.

There was formerly only one measure of capacity in Scotland; and some commodities were heaped, others *straked*, or measured exactly to the capacity of the standard. The method of heaping was afterwards forbidden, as unequal, and a larger measure appointed for such commodities as that custom had been extended to.

The wheat-firiot, used also for rye, pease, beans, salt, and grass-seeds, contains 21 pints 1 mutchkin, measured by the Stirling jug. The barley-firiot, used also for oats, fruit, and potatoes, contains 31 pints. A different method of regulating the firiot was appointed, from the dimensions of a cylindrical vessel. The diameter for both measures was fixed at $19\frac{1}{2}$ inches, the depth $7\frac{1}{2}$ inches for the wheat-firiot, and $10\frac{1}{2}$ for the barley-firiot. A standard constructed by these measures is rather less than when regulated by the pint; and as it is difficult to make vessels exactly cylindrical, the regulation by the pint has prevailed, and the other method gone into disuse.

If the Stirling jug contain $103\frac{1}{2}$ inches, the wheat-firiot will contain 2109 inches; which is more than 2 per cent. larger than the legal malt-bushel of England, and about 1 per cent. larger than the Winchester bushel: and the barley-firiot will contain 3208 inches. The barley-boll is nearly equal to six legal malt bushels.

In Stirlingshire, 17 pecks are reckoned to the boll: in Invernesshire, 18 pecks: in Ayrshire, the boll is the same as the English quarter. And the firlots, in many places, are larger than the Linlithgow standard.

40 feet hewn timber make a load.
 50 feet unhewn timber make a load.
 32 gallons make a herring barrel.
 42 gallons make a salmon barrel.
 1 cwt. gun-powder makes a barrel.
 256 lb. soap make a barrel.
 10 dozen candles make a barrel.
 12 barrels make a laft.

Medicine MEDICINE, n^o 494. See further the article SEP-
PENT, in this APPENDIX.

Mine. MEDINE, an Egyptian piece of money, of iron
silvered over, and about the size of a silver threepence.

MERCURY. Line 2. for 214, read 414.

MERCURIFICATION, in metallurgic chemi-
stry, the obtaining the mercury from metallic minerals
in its fluid form. For the effecting this, those who
have been engaged in these researches have proposed
three methods. The first is by means of a certain
mercury, so prepared as to have a dissolving power,
by which it could take up the mercuries of metals in
the same manner as water dissolves salt from ashes.
The second is by means of certain regenerating salts,
such as sal ammoniac, which are to detain the more
earthy parts of metals, and leave their mercuries se-
parate or separable from them by sublimation or other-
wise; and the third method is by means of a large lens
or burning-glass, in the focus whereof, if any metal be
applied, its mercurial part is said to separate and go off
in fume, which when collected and condensed, appears
to be running mercury.

The first of these methods would be very easy if the
proper mercury were to be readily produced; the se-
cond is extremely laborious, and requires much pa-
tience and reiteration. But the third seems easy e-
nough, and practicable to advantage, when a glass of
three or four feet in diameter is at hand, the sky serene,
and the sun shines strong.

For other processes, the reader may consult Junker's
Conspectus Chemicæ. But these mercurified metals, or
their mercurial principle rendered sensible, are a kind
of philosophical mercury, which, although they re-
semble ordinary mercury, are nevertheless said by per-
sons exercised in such studies, to differ from it consi-
derably, by having a greater specific gravity, by more
effectually penetrating and dissolving metals, by a
stronger adhesion to these, and by a less volatility.

MILLEPORA, in natural history, a name by
which Linnæus distinguishes that genus of lithophytes,
of a hard structure and full of holes, which are not
stellate or radiated, and whose animal is the hydra, in
which it differs from the madrepora, and comprehend-
ing 14 different species.

In the millepora, the animal which forms and inha-
bits it occupies the substance; and it is observed that
the milleporæ grow upon one another: their little ani-
mals produce their spawn; which attaching itself ei-
ther to the extremity of the body already formed, or
underneath it, gives a different form to this produc-
tion. Hence the various shapes of the millepora,
which is composed of an infinite number of the cells of
those little insects, which all together exhibit different
figures, though every particular cellula has its essen-
tial form, and the same dimensions, according to its
own species.

MINE, in the military art, (*Encycl.*) Mines are
either dug within the body of the earth, as those made
by the besieged to blow up the works of the besiegers
before they make a lodgment on the covered way; or
in eminences and rising grounds, as to make a breach
in the ramparts, &c. or to blow up walls, or, lastly,
to tear up rocks.

Two ounces of powder have been found, by experi-
ment, capable of raising two cubic feet of earth; con-

sequently 200 ounces, that is, 12 pound 8 ounces,
will raise 200 cubic feet, which is only 16 feet short
of a cubic toise, because 200 ounces joined together
have proportionably a greater force than 2 ounces, as
being an united force.

All the turnings a miner uses to carry on his mines,
and through which he conducts the faucille, should be
well filled with earth and dung; and the masonry in
proportion to the earth to be blown up, as 3 to 2.
The entrance of the chamber of the mine ought to be
firmly shut with thick planks, in the form of a St An-
drew's cross, so that the inclosure be secure, and the
void spaces shut up with dung or tempered earth. If
a gallery be made below or on the side of the chamber,
it must absolutely be filled up with the strongest ma-
sonry, half as long again as the height of the earth;
for this gallery will not only burst, but likewise ob-
struct the effect of the mine. The powder should al-
ways be kept in sacks, which are opened when the
mine is charged, and some of the powder threwed
about: the greater the quantity of earth to be raised
is, the greater is the effect of the mine, supposing it
to have the due proportion of powder. Powder has
the same effect upon masonry as upon earth, that is,
it will proportionably raise either with the same ve-
locity.

The branches which are carried into the solidity of
walls do not exceed three feet in depth, and two feet
six inches in width nearly: this sort of mine is most
excellent to blow up the strongest walls.

The weight of a cubic foot of powder should be
80lb. 1 foot 1 inch cube will weigh 100lb. and 1 foot
2 inches and $\frac{1}{2}$, 150lb. and 200lb. of powder will be
1 foot 5 inches cube; however, there is a diversity in
this, according to the quantity of saltpetre in the gun-
powder.

If, when the mines are made, water be found at the
bottom of the chamber, planks are laid there, on
which the powder is placed either in sacks or barrels,
of 100lb. each. The faucille must have a clear passage
to the powder, and be laid in an auget or wooden
trough, through all the branches. When the powder
is placed in the chamber, the planks are laid to cover
it, and others again across these; then one is placed
over the top of the chamber, which is shaped for that
purpose: between that and those which cover the
powder, props are placed, which shore it up; some
inclining towards the outside, others to the inside of
the wall; all the void spaces being filled with earth,
dung, brick, and rough stones. Afterwards planks are
placed at the entrance of the chamber, with one across
the top, whereon they buttress three strong props,
whose other ends are likewise propped against another
plank situated on the side of the earth in the branch;
which props being well fixed between the planks with
wedges, the branch should then be filled up to its en-
trance with the forementioned materials. The faucilles
which pass through the side-branches must be exactly
the same length with that in the middle, to which they
join: the part which reaches beyond the entrance of
the mine is that which conveys the fire to the other
three; the faucilles being of equal length, will spring
together. From a great number of experiments, it
appears, 1. That the force of a mine is always towards
the weakest side; so that the disposition of the cham-
ber

BYSSI.

USNEÆ.

TERMES.

FONTINALIS.

ber of a mine does not at all contribute to determine this effect. 2. That the quantity of powder must be greater or less, in proportion to the greater or less weight of the bodies to be raised, and to their greater or less cohesion; so that you are to allow for each cubic fathom

| | | |
|----------------------------------|---|-------------|
| Of loose earth, | - | 9 or 10 lb. |
| Firm earth and strong sand, | - | 11 or 12 |
| Fat clayey earth, | - | 15 or 16 |
| New masonry, not strongly bound, | - | 15 or 20 |
| Old masonry, well bound, | - | 25 or 30 |

3. That the aperture, or entonnoir of a mine, if rightly charged, is a cone, the diameter of whose base is double the height taken from the centre of the mine.

4. That when the mine has been overcharged, its entonnoir is nearly cylindrical, the diameter of the upper extreme not much exceeding that of the chamber.

5. That besides the shock of the powder against the bodies it takes up, it likewise crushes all the earth that borders upon it, both underneath and sideways.

To charge a mine so as to have the most advantageous effect, the weight of the matter to be carried must be known; that is, the solidity of a right cone, whose base is double the height of the earth over the centre of the mine: thus, having found the solidity of the cone in cubic fathoms, multiply the number of fathoms by the number of pounds of powder necessary for raising the matter it contains; and if the cone contains matters of different weights, take a mean weight between them all, always having a regard to their degree of cohesion.

As to the disposition of mines, there is but one general rule, which is, that the side towards which one would determine the effect be the weakest; but this varies according to occasions and circumstances.

The calculation of mines is generally built upon this hypothesis, That the entonnoir of a mine is the frustum of an inverted cone, whose altitude is equal to the radius of the excavation of the mine, and the diameter of the whole lesser base is equal to the line of least resistance; and though these suppositions are not quite exact, yet the calculations of mines deduced from them have proved successful in practice; for which reason this calculation should be followed, till a better and more simple be found out.

M. de Valliere found that the entonnoir of a mine was a paraboloid, which is a solid generated by the rotation of a semiparabola about its axis; but as the difference between these two is very insignificant in practice, that of the frustum of a cone may be used.

MINERALOGY, (*Encycl.*) P. 5065, line 13. from the bottom, for *n m v*, mark *d e f*; and line 5. from the bottom, after *acids*, supply "mentioned, n° 68."

MORGO, anciently *Amorgos*, an island in the Archipelago, fertile in wine, oil, and corn. It is well cultivated, and the inhabitants are affable, and generally of the Greek church. The best parts belong to a monastery. The greatest inconvenience in this island is the want of wood. It is 30 miles in circumference. E. Long. 26. 15. N. Lat. 36. 30.

MOSES, (*Encycl.*) Moyses, by the inconsiderate mind, are generally deemed an useless or insignificant part of the creation. That they are not, is evident from hence; that he who made them has made no-

thing in vain, but on the contrary has pronounced all his works to be very good. Many of their uses we know; that they have many more which we know not, is unquestionable, since there is probably no one thing in the universe of which we dare to assert that we know all their uses. Thus much we are certain of with respect to mosses, that as they flourish most in winter, and at that time cover the ground with a beautiful green carpet, in many places which would be otherwise naked, and when little verdure is elsewhere to be seen; so at the same time they shelter and preserve the seeds, roots, gems, and embryo plants of many vegetables, which would otherwise perish; they furnish materials for birds to build their nests with; they afford a warm winter's retreat for some quadrupeds, such as bears, dormice, and the like, and for numberless insects, which are the food of birds and fishes, and these again the food or delight of men. Many of them grow on rocks and barren places, and rotting away afford the first principles of vegetation to other plants, which could never else have taken root there. Others grow in bogs and marshes, and, by continual increase and decay, fill up and convert them either into fertile pastures, or into peat-bogs the source of inexhaustible fuel to the polar regions.—They are applicable also to many domestic purposes: the lycopodiums are some of them used in dyeing of yarn, and in medicine; the sphagnum and polytrichum furnish convenient beds for the Laplanders; the hypnum are used in tiling of houses, stopping crevices in walls, packing up of brittle wares and the roots of plants for distant conveyance.—To which may be added, that all in general contribute entertainment and agreeable instruction to the contemplative mind of the naturalist, at a season when few other plants offer themselves to his view.

MOATAZALITES, or SEPARATISTS, a religious sect among the Turks, who deny all forms and qualities in the Divine Being; or who divest God of his attributes.

There are two opinions among the Turkish divines concerning God. The first admits metaphysical forms, or attributes; as, that God has wisdom, by which he is wise; power, by which he is powerful; eternity, by which he is eternal, &c.

The second allows God to be wise, powerful, eternal; but will not allow any form or quality in God, for fear of admitting a multiplicity.

Those who follow this latter opinion are called *Moatazalites*; they who follow the former, *Sephalites*.

The Moatazalites also believed that the word of God was created in *subiecto*, as the schoolmen term it, and to consist of letters and sound; copies thereof being written in books to express or imitate the original; they denied absolute predestination, and affirmed that man is a free agent. This sect is said to have first invented the scholastic divinity, and is subdivided into no less than 20 inferior sects, which mutually brand one another with infidelity.

MUNDA, (*Encycl.*) This city was anciently famous for a victory gained by Cæsar over the sons of Pompey, who had collected an army in Spain after the defeat of their father at Pharsalia. An account of the battle was referred from ROME, n° 218. to MUNDA, but omitted.

Mosses
||
Munda.

The Pompeys pushed their army advantageously upon a rising ground, whereof one side was defended by the city of Munda, and the other by a small river which watered the plain, and by a marsh; so that the enemy could not attack them but in front. Cæsar likewise drew up his troops with great art, and having advanced a little way from his camp, ordered them to halt, expecting the enemy would abandon their advantageous post, and come to meet him. But as they did not stir, Cæsar made as if he intended to fortify himself in that post; which induced the young general, who looked upon this as a sign of fear, to advance into the plain, and attack the enemy before they could secure themselves with any works. Pompey's army was by far the most numerous; for it consisted of 13 legions, 6000 horse, and an incredible number of auxiliaries, among whom were all the forces of Bocchus king of Mauritania, commanded by his two sons, both youths of great valour and bravery. Cæsar had 80 cohorts, three legions, to wit, the third, the fifth, and the tenth, and a body of 8000 horse. As the enemy drew near, Cæsar betrayed a great deal of uneasiness and concern, as if he were doubtful of the success, knowing he was to engage men no way inferior in valour and experience to his own, and commanded by officers who had on many occasions given signal proofs of their bravery and conduct. Cocæus, the elder of the two brothers, was generally looked upon as an able commander; and Labienus, who had revolted, esteemed scarce inferior to Cæsar himself.

However, the dictator, desirous to put an end to the civil war, either by his own death, or that of his rivals, gave the signal for the battle, and fell upon the enemy with his usual vigour and resolution. At the first onset, which was dreadful, the auxiliaries on both sides betook themselves to flight, leaving the Romans to decide their quarrel by themselves. Then the legionaries engaged, with a fury hardly to be expressed; Cæsar's men being encouraged by the hopes of putting an end to all their labours by this battle, and those of Pompey exerting themselves out of necessity and despair, since most of them expected no quarter, as having been formerly pardoned. Never was victory more obstinately disputed. Cæsar's men, who had been always used to conquer, found themselves so vigorously charged by the enemy's legionaries, that they began to give ground; and though they did not turn their backs, yet it was manifest that shame alone kept them in their posts. All authors agree, that Cæsar had never been in so great danger; and he himself, when he came back to his camp, told his friends, that he had often fought for victory, but this was the first time he had ever fought for life. Thinking himself abandoned by fortune, which had hitherto favoured him, he had some thoughts of stabbing himself with his own sword, and, by a voluntary death, preventing the disgrace of a defeat: but returning soon to himself, and concluding it would be more to his reputation to fall by the enemy's hand at the head of his troops, than, in a fit of despair, by his own, he dismounted from his horse, and snatching a buckler from one of his legionaries, he threw himself, like a man in despair, into the midst of the enemy; crying out to his men, *Are you not ashamed to deliver your general into the hands of boys?* At these words, the sol-

diers of the tenth legion, animated by the example of their general, fell upon the enemy with fresh vigour, and made a dreadful havoc of them. But, in spite of their utmost efforts, Pompey's men still kept their ground, and, though greatly fatigued, returned to the charge with equal vigour. Then the Cæsarians began to despair of victory; and the dictator, running thro' the ranks of his disheartened legionaries, had much ado to keep them together. The battle had already lasted from the rising to the setting of the sun, without any considerable advantage on either side.

At length a mere accident decided the dispute in favour of the dictator. Bogud, a petty king of Mauritania, had joined Cæsar, soon after his arrival in Spain, with some squadrons of Numidian horse; but, in the very beginning of the battle, being terrified at the shouting of the soldiers, intermingled with groans, and the clashing of their arms, he had abandoned his post, and retired with the auxiliaries under his command to a rising ground at a small distance from the enemy's camp. There he continued the whole day an idle spectator of the battle that was fought in the plain. But towards the evening, partly out of shame, and partly out of compassion for his friend Cæsar, he resolved to fall upon Pompey's camp; and accordingly flew thither with all the forces he had with him. Labienus, apprised of his design, hastened after him, to the defence of the camp; which Cæsar observing, cried to his legionaries, *Courage, fellow-soldiers! the victory at length is ours; Labienus flies.* This artifice had the desired effect: Cæsar's men, believing that Labienus was truly fled, made a last effort, and charged the wing he commanded so briskly, that after a most obstinate dispute they put them to flight.

Though the enemy's left wing was thus entirely defeated, the right wing, where the elder Pompey commanded, still kept their ground for some time. Pompey dismounting from his horse, fought on foot like a private man in the first line, till most of his legionaries being killed, he was forced to save himself by flight from falling into the enemy's hands. Part of his troops fled back to their camp, and part took shelter in the city of Munda. The camp was immediately attacked, and taken sword in hand; and as for the city, Cæsar, without loss of time, drew a line of circumvallation round it. This victory was gained on the 16th of the calends of April, i. e. according to our way of counting, on the 17th day of March, when the Dionysian festival, or the Liberalia, were celebrated at Rome; the very day, as Plutarch observes, in which Pompey the Great, four years before, had set out for the war. In this action Pompey lost 30,000 men; among whom were the famous Labienus, Attius Varus, and 3000 Roman knights. Seventeen officers of distinction were taken, and all the enemy's eagles and ensigns, together with Pompey's sables, which he had assumed as governor of Spain. On Cæsar's side only 1000 men were killed, and 500 wounded.

MULLEIN, VERBASCUM, (*Encyel.*) White mullein has received the name of *cow's lungwort*, from the great reputation it had formerly among the country people for inveterate coughs among the horned cattle. Parkinson tells us, that in his time it was used in such cases with great success. It still retains the same credit in several parts of Europe.

MUSCA,

MUSCA, (*Encycl.*) Line 1. for *gnat*, read *fly*.

Flies form one of the most numerous classes of insects. Variety runs through their forms, their structure, their organization, their metamorphoses, their manner of living, propagating their species, and providing for their posterity. Every species is furnished with implements, adapted to its exigencies. What exquisite-ness, what proportion, in the several parts that compose the body of a fly! What precision, what mechanism in the springs and motion! Some are oviparous, others viviparous; which latter have but two young ones at a time, whereas the propagation of the former is by hundreds. Flies are lascivious, troublesome insects, that put up with every kind of food. When storms impend, they have most activity, and sting with greatest force. They multiply most in hot moist climates; and so great was formerly their numbers in Spain, that there were fly-hunters commissioned to give them chase. The vapour of sulphur or arsenic destroys them; and their numbers may be reduced by taking them in phials of honeyed water, or between boards done over with honey.

MYA MARGARITIFERA, (*Encycl.*) Linnæus has made a remarkable discovery relating to the generation of pearls in this fish. This must not be confounded with what is called the *mother-of-pearl shell*, as that belongs to another genus, is a sea-shell, and an inhabitant of the warmer countries only. The shell-fish in question is found in rivers in all the northern parts of the world; in Norway and Sweden it abounds; it is found in the rivers of the county of Tyrone in Ireland, and in those of Donegal; in Scotland, the Don is said to abound with it; and it is not unfrequent in the rivers of England. This fish will bear removal remarkably well; and it is said, that in some places they form reservoirs for the purpose of keeping it, and taking out the pearl, which, in a certain period of time, will be again renewed. From observations on the growth of these shells, and the number of their annular laminae, or scales, it is supposed the fish will attain a very great age; 50 or 60 years are imagined to be a

moderate computation. The discovery turned on a method which Linnæus found, of putting these muscles into a state of producing pearls at his pleasure; though the final effect did not take place for several years: He says, that in five or six years after the operation the pearl would have acquired the size of a vetch. We are unacquainted with the means by which he accomplished this extraordinary operation; but it was probably published at the time, and considered as important, since it is certain that the author was rewarded with a munificent premium from the States of the kingdom on this account. We regret that we cannot speak more fully on this head; but may observe, that it is probable, from a paper published many years afterwards in the Berlin Acts, that the method consisted in injuring the shell externally, perhaps by a perforation; as it has been observed, that these concretions in shell-fish are found on the inside, exactly opposite to perforations and injuries made from without by serpulae and other animals.

MYCETITES DISCOIDES, in natural history, a name given by Dr Woodward to those kinds of fossil coralloide bodies which the generality of writers had called, after Dr Plott, *porpita*. These are usually small, and of a roundish, but flattened figure; they are hollowed on one side with a sort of umbilicus, and striated on the other; they are found on the ploughed lands in Oxfordshire, and some other of our midland counties, and in other places, buried in the solid strata of stone; they are sometimes yellowish, sometimes brownish, and are from the breadth of an inch to a fourth part or less of that size; when broken, they are usually found to consist of a kind of spar, not unlike that of which the shelly coats of the echinite, or the lapides indici, and other spines of echini consist in their fossil state; and in some of them the ridges and striæ are thick set with little knobs and tubercles. The basis in some of these is flat, as it is in others rising in form of a circular elevation from the umbilicus, and others have a circular cavity in the same place.

Mycetites,
Necessity.

N.

NARVA, a strong town of the Russian empire, in Livonia, with a castle, and a harbour. It was taken by the Muscovites from the Danes in 1558, by the Swedes in 1581, and they defeated the Muscovites near it in 1700; but it was retaken by the Russians in 1704, by storm, and the inhabitants sent to Astrachan. It is seated on the river Narva, 95 miles S. W. of Wiburgh, and 172 N. E. of Riga. E. Long. 29. o. N. Lat. 59. 8.

NECESSITY, (*Encycl.*) Mr Hobbes, who is said to have been the first who understood and maintained the proper doctrine of philosophical necessity, gives the following account of it in his *Leviathan*, p. 108. Liberty and necessity are consistent; as in the water, that hath not the liberty, but a necessity of descending in the channel: so likewise in the actions which men voluntarily do, which, because they proceed from their will, proceed from liberty; and yet, because every act of man's will, and every desire and inclination, proceedeth from some cause, and that from another cause, in a continual

chain (whose first link is in the hand of God, the first of all causes), proceed from necessity; so that to him who could see the connection of those causes, the necessity of all men's voluntary actions would appear manifest: and therefore God that seeth and disposeth all things, seeth also, that the liberty of man, in doing what he will, is accompanied with the necessity of doing that which God will, and no more or less: for though men may do many things, which God does not command, nor is, therefore, the author of them, yet they can have no passion, will, or appetite to any thing, of which appetite God's will is not the cause: and did not his will assure the necessity of man's will, and consequently of all that on man's will dependeth, the liberty of men would be a contradiction and impediment to the omnipotence and liberty of God.

Mr Collins, one of the most admired writers on the subject of necessity, has stated the question concerning human liberty in the following manner. Man, he says, is a necessary agent, if all his actions are so determined by the causes preceding each action, that not one past

action could possibly not have come to pass, or have been otherwise than it hath been; nor one future action can possibly not come to pass, or be otherwise than it shall be. But he is a free agent, if he is able, at any time, under the circumstances and causes he then is, to do different things; or, in other words, if he is not unavoidably determined, in every point of time, by the circumstances he is in, and causes he is under, to do that one thing he does, and not possibly to do any other. According to this state of the question, he undertakes to prove, that man is a necessary agent; and that there neither is nor can be such a thing as liberty.

1. He appeals to experience; alleging, that though the vulgar urge this in proof of liberty, it is not a proof of it: that many celebrated philosophers and theologians, both ancient and modern, have given definitions of liberty, that are consistent with fate or necessity: that some great patrons of liberty do, by their concessions in this matter, destroy all arguments from experience: that all the actions of men may be ranked under the four heads of perception, judging, willing, and and doing as we will; and that experience does not prove any of these to be free; and that experience not only does not prove liberty, but, on the contrary, men may see by experience, that they are necessary agents. It is, says he, matter of experience, that man is ever determined in his willing: we experience perfect necessity: and they, who think liberty a matter of experience, yet allow that the will follows the judgment of the understanding; and that, when two objects are presented to a man's choice, one whereof appears better than the other, he cannot chuse the worst.

2. Man is a necessary agent, because all his actions have a beginning; for whatever has a beginning must have a cause, and every cause is a necessary cause; and if any action whatsoever can be done without a cause, then effects and causes have no necessary relation; and, consequently, we should not be necessarily determined in any case at all.

3. Liberty would not be a perfection, but an imperfection; whereas, on the contrary, necessity is an advantage and a perfection.

4. Liberty is inconsistent with the divine prescience; for if God foreknows the existence of any thing, as it depends on its own causes, that existence is no less necessary than if it were the effect of his decree: for it no less implies a contradiction, that causes should not produce their effects, than that an event should not come to pass which is decreed by God.

This last argument for necessity has been urged by a variety of writers; and the advocates for liberty have felt its force, and endeavoured to obviate it. Some have actually given up the divine prescience: some have allowed the seeming contradiction implied in the foreknowledge of a contingent event, and have acknowledged themselves incapable of removing it. Others have endeavoured to reconcile the foreknowledge of God and the liberty of man, by alleging, that there is a great difference between God's foreknowledge and his decrees, with regard to the necessity of future events; for God's prescience has no influence at all on our actions: his infallible judgment, concerning contingent truths, does no more alter the nature of the things, and cause them to be necessary, than our judging right, at any time, concerning a contingent truth,

makes it cease to be contingent; or, than our sense of a present truth is any cause of its being true or present.

In the argument, says Dr Clarke, drawn against liberty from the divine prescience, it must not first be supposed that things are in their own nature necessary; but from the divine prescience or power of judging infallibly (which power is as much more extensive and infallible than in man, as the divine nature and understanding are superior to ours) concerning free events, it must be proved, that things otherwise supposed free, will therefore unavoidably become necessary; which can no more be proved, than it can be proved that an action, supposed at this present time to be free, is yet (contrary to the supposition) at the same time necessary; because, in all past time, whether foreknown or not foreknown, it could not, upon that very supposition of its being now freely done, be free.

In another place, he acknowledges, that, though it is impossible for us to explain distinctly the manner how God can foresee future events without a chain of necessary causes, yet we may form some general notion of it. For, as a man, who has no influence over another person's actions, and yet often perceives before hand what that other will do; and a wiser and more experienced man will still, with greater probability, foresee what another, whose disposition he is perfectly acquainted with, will in certain circumstances do; and an angel, with still much less degree of error, may have a farther prospect into mens future actions: so it is very reasonable to apprehend, that God, without influencing mens wills by his power, yet by his foresight cannot but have as much more certain a knowledge of future free events than either men or angels can possibly have, as the perfection of his nature is greater than that of theirs. The certainty of foreknowledge, says this excellent writer, does not cause the certainty of things, but is itself founded on the reality of their existence; nor does it imply any other certainty than such as would be equally in things, tho' there was no foreknowledge; nor again does this certainty of event, in any sort, imply necessity. To the same purpose Origen has long ago observed, that prescience is not the cause of things future, but their being future is the cause of God's prescience that they will be.

It cannot reasonably be disputed, that there is an essential difference between the foreknowledge and permission of events, and the preordination and production of them: and the scheme of necessity seems directly to charge God with being the efficient cause or author of those vices and evils which arise from circumstances and connections of his previous and absolute appointment. Indeed, many of the advocates of this scheme will not admit the consequence that seems to be fairly deducible from their opinion: however, Dr Priestley very candidly allows it. It certainly (says he) sounds harsh to vulgar ears to say, that in all those crimes that men charge themselves with, and reproach themselves for, God is the agent; and that, in such cases, they are in reality no more agents, than a sword is an agent when employed to commit a murder. It does require strength of mind not to startle at such a conclusion; but then it requires nothing but strength of mind; i. e. such a

view of things as shall carry us beyond first and fallacious appearances.

5. Another argument in favour of necessity is the following: if man was not a necessary agent, determined by pleasure and pain, there would be no foundation of rewards and punishments, which are the essential supports of society. These would be useless, because if men were free or indifferent to pleasure and pain, they could be no motives to a man to do or forbear any action.

6. Another argument of the same kind is deduced from the nature of morality: for if man was not a necessary agent, determined by pleasure and pain, he would have no notion of morality, or motive to practise it; and if he were indifferent to pleasure and pain, he would have no rule to go by, and might never judge, will, and practise right. Every act of the will, it is said, is excited by some motive, which motive is the cause of that act: and if volitions are properly the effects of motives, then they are necessarily connected with their motives: whence it is inferred, that volition is necessary, and doth not proceed from any self-determining power in the will. This argument has been illustrated and urged in all its force by many modern writers, from M. Leibnitz to Dr Priestley, the last and most zealous advocate for necessity: and it has often been answered by Dr Clarke and others, who have strenuously maintained, that liberty is perfectly consistent with mens acting from a regard to motives.

Supposing, says Dr Price, a power of self-determination to exist, it is by no means necessary that it should be exerted without a regard to any end or rule: on the contrary, it can never be exerted without some view or design. Whoever acts, means to do somewhat. The power of determining ourselves, by the very nature of it, wants an end or rule to guide it; and no probability or certainty of its being exerted agreeably to a rule can have the least tendency to infringe or diminish it. All that should be avoided here is the intolerable absurdity of making our reasons and ends, in acting, the physical causes or efficient of action. This is the same with ascribing the action of walking, not to the feet, or the power which moves the feet, but to the eye, which only sees the way. The perception of a reason for acting, or the judgment of the understanding, is no more than seeing the way; it is the eye of the mind which informs and directs; and whatever certainty there may be that a particular determination will follow, such determination will be the self-determination of the mind; and not any change of its state stamped upon it, over which it has no power, and in receiving which, instead of being an agent, it is merely a passive subject of agency. Although the views and ideas of beings may be the occasions of their acting; yet it is a contradiction to make them the mechanical efficient of their actions: so necessary and important is the distinction insisted upon by Dr Clarke, between the operation of physical causes and the influence of moral reasons.

Upon the whole, the question concerning liberty is not, Whether the views or ideas of beings influence their actions; but, What is the nature of that influence. If we say, that it is some kind of mechanical or physical efficiency; or, with Dr Priestley, after Hobbes

and Leibnitz, that man has no other liberty, in following motives, than water has in running down hill, or than the arms of a scale, pressed by weights, have in rising and falling; then it must follow, that man never acts, and it must be folly to applaud or reproach ourselves for our conduct, and there is an end of all moral obligation and accountableness.

However, the necessitarians do not allow these consequences; but, on the contrary, maintain, that the doctrine of the necessary influence of motives upon the mind of man, makes him the proper subject of discipline, reward, and punishment, praise and blame, both in the common and the philosophical use of the words; and that the doctrine of self-determination, independently of the influence of motives, entirely disqualifies a man from being the proper subject of them.

Mr Edwards, an acute writer on this subject, has endeavoured to prove, that liberty of indifference is not only not necessary to virtue, but utterly inconsistent with it; and that all habits and inclinations, whether virtuous or vicious, are inconsistent with the Arminian notions of liberty and moral agency. And Dr Priestley observes, that the sense of self-reproach and shame is excited by our finding that we have a disposition of mind leading to vice, and on which motives to virtue, in particular cases, have had no influence. If we ask, whence proceeds that disposition, and how it comes to pass that motives to virtue had not a greater influence, we must ultimately ascribe the inefficacy of the one, and the evil tendency of the other, to God, who made us what we are, and placed us in the situation which we occupy. Dr Priestley overcomes this difficulty by alleging, that the distinction between things natural and moral entirely ceases in the scheme of necessity; that the vices of men come under the class of common evils, producing misery for a time, but, like all other evils, in the same great system, ultimately subservient to greater good. In this light, he says, every thing without distinction may be ascribed to God. However, he acknowledges, that this is a view of moral evil, which, though innocent, and even useful, in speculation, no wise man can or would choose to act upon himself, because our understandings are too limited for the application of such a means of good; though a Being of infinite knowledge may introduce it with the greatest advantage. If there be any foundation for the doctrine of necessity, i. e. if all events arise from preceding situations, and the original situations of all things, together with the laws by which all changes of situation take place, were fixed by the Divine Being, there can be no difference whatever with respect to his causation of one thing more than another; and even whatever takes place in consequence of his withholding his special and extraordinary influence, is as much agreeable to his will as what comes to pass in consequence of the general laws of nature. But our supposing that God is the author of sin, (as by the scheme of necessity he must in fact be the author of all things), by no means implies that he is a sinful being; for it is the disposition of mind and the design which constitute the sinfulness of an action. If therefore his disposition and design be good, what he does is morally good. To the same purpose he observes, that the proper foundation, or rather the

ultimate object, of virtue, is general utility; since it consists of such conduct as tends to make intelligent creatures the most truly happy in the whole of their existence; though, with respect to the agent, no action is denominated virtuous that is not voluntary, or that does not proceed from some good motive. And this reasoning he applies to the Deity, who pursues the happiness of his creatures by such means as are best calculated to secure that end, and which are sanctified by it. And he further adds, that the Deity may adopt some things which he would not have chosen on their own account, but for the sake of other things with which they were necessarily connected.

The scriptures, according to this last writer, are favourable to the doctrine of necessity; though he does not think that the sacred writers were, strictly speaking, necessarians, for they were not philosophers: but their habitual devotion led them to refer all things to God, without reflecting on the rigorous meaning of their language: and very probably, had they been interrogated on the subject, they would have appeared not to be apprised of the proper extent of the necessary scheme, and would have answered in a manner unfavourable to it.

The reader, who is desirous of being farther acquainted with the reasoning of different writers on this subject, may consult the collection of papers between Leibnitz and Clarke, 1717. Collins's Philosophical Inquiry concerning Human Liberty, 1735, 3d Ed. with Clarke's Answer. Edwards on the Freedom of the Will, 8vo, 1775, 4th edit. Priestley's Doctrine of Philosophical Necessity, 8vo, 1777. Correspondence between Dr Price and Dr Priestley, 8vo, 1778. Hartley's Observations on Man, 8vo, 1749. See LIBERTY, (*Append.*)

NEREIS, (*Encycl.*) The head of this insect is roundish, flattened, with the rostrum extending to a point; tentacula (feelers) two, very short, subulate; eyes, two, prominent, on the sides of the head; body consisting of 23 segments, diminishing toward the tail; the side of every segment has a conical apex cut short at the vertex, and denticulated; from which springs a small pencil of hairs, under each pencil a filament resembling a foot, subulate, flexible, unarmed. Colour, glassy, pellucid. Length, two lines. Habitation, sea-plants, as the fuci and alga, which sometimes it leaves, and wanders on the surface of the sea.

This insect is frequent in all seasons of the year, but particularly in summer, and on the approach of a tempest, when it seems through inquietude to give a much greater quantity of light; its appearance also is very brilliant when the wind is in the east and south-east points, and in winter-nights preceded by a warm day. If water containing these animacules be kept warm, they retain their light two whole days after they are dead; but in cold weather lose it in eight hours: motion and warmth, which increase their vivacity and strength, increase their light also.

NEWTON (Bishop), late lord bishop of Bristol and dean of St Paul's, London, was born on the first of January 1704. His father, John Newton, was a considerable brandy and cyder merchant, who, by his industry and integrity, having acquired what he thought a competent fortune, left off trade several years before he died.

He received the first part of his education in the free school of Litchfield; a school which, the bishop observes with some kind of exultation, had at all times sent forth several persons of note and eminence; from bishop Smalbridge and Mr Wollaston, to Dr Johnson and Mr Garrick.

From Litchfield he was removed to Westminster-school, in 1717, under the care of Dr Freind and Dr Nicoll.

During the time he was at Westminster, there were, he observes, more young men who made a distinguished figure afterwards in the world, than perhaps at any other period, either before or since. He particularly mentions William Murray, the present earl of Mansfield, with whom he lived on terms of the highest friendship to the last.

He continued six years at Westminster-school, five of which he passed in college. He went to Cambridge, and entered at Trinity college. Here he constantly resided eight months at least in every year, till he had taken his Bachelor of Arts degree. Soon after he was chosen Fellow of Trinity college, he came to settle in London. As it had been his inclination from a child, and he was also designed for holy orders, he had sufficient time to prepare himself, and composed some sermons, that he might have a stock in hand when he entered on the ministry. His title for orders was his fellowship; and he was ordained deacon in December 1729, and priest in the February following, by bishop Gibson.

At his first setting out in the world, he officiated as curate at St George's, Hanover-square; and continued for several years assistant-preacher to Dr Trebeck. His first preferment was that of reader and afternoon-preacher at Grosvenor chapel, in South-Audley street.

This introduced him to the family of lord Tyrconnel, to whose son he became tutor. He continued in this situation for many years, very much at his ease, and on terms of great intimacy and friendship with lord and lady Tyrconnel, "without so much (says he) as an unkind word or a cool look ever intervening."

In the spring of 1744, he was, through the interest of the earl of Bath (who was his great friend and patron, and whose friendship and patronage were returned by grateful acknowledgments and the warmest encomiums) presented to the rectory of St Mary le Bow; so that he was 40 years old before he obtained any living.

At the commencement in 1745, he took his Doctor's degree. In the spring of 1747 he was chosen lecturer of St George's Hanover-square, by a most respectable vestry of noblemen and gentlemen of high distinction. In August following he married his first wife, the eldest daughter of Dr Trebeck, an unaffected, modest, decent young woman, with whom he lived very happy, in mutual love and harmony, near seven years.

In 1749 he published his edition of Milton's Paradise Lost, which (says he, very modestly) it is hoped hath not been ill received by the public, having, in 1775, gone through eight editions. After the Paradise Lost, it was judged (says he) proper that Dr Newton should also publish the Paradise Regained, and other poems of Milton; but these things he thought detained him from other more material studies, though he had the good fortune to gain by them more than

Milton,

Milton did by all his works put together. But his greatest gain (he says) was their first introducing him to the friendship and intimacy of two such men as bishop Warburton and Dr Jortin, whose works will speak for them better than any private commendation.

In 1754 he lost his father, at the age of 83; and within a few days his wife, at the age of 38. This was the severest trial he ever underwent, and almost overwhelmed him. At that time he was engaged in writing his *Dissertations on the Prophecies*; and happy it was for him: for in any affliction he never found a better or more effectual remedy, than plunging deep into study, and fixing his thoughts as intensely as he possibly could upon other subjects. The first volume was published the following winter; but the other did not appear till three years afterwards, as, for the encouragement of his work, he was appointed, in the mean time, to preach the Boyle's lecture. The bishop informs us, that 1250 copies of the *Dissertations* were taken at the first impression, and 1000 at every other edition: and "though (says he) some things have been since published upon the same subjects, yet they still hold up their head above water, and having gone through five editions, are ready prepared for another. Abroad, too, their reception hath not been unfavourable, if accounts from thence may be depended upon." They were translated into the German and Danish languages; and received the warmest encomiums from persons of learning and rank.

In the spring of 1757, he was made prebendary of Westminster, in the room of Dr Green, and promoted to the deanery of Salisbury. In October following, he was made sub-almoner to his majesty. This he owed to bishop Gilbert. He married a second wife in September 1761. She was the widow of the Rev. Mr Hand; and daughter of John lord viscount Lisburne. In the same month he kissed his majesty's hand for his bishopric.

In the winter of 1764, Dr Stone, the primate of Ireland, died. Mr Grenville sent for bishop Newton, and in the most obliging manner desired his acceptance of the primacy. Having maturely weighed the matter in his mind, he declined the offer.

In 1768 he was made dean of St Paul's. His ambition was now fully satisfied; and he firmly resolved never to seek or ask for any thing more.

From this time to his death, ill health was almost his constant companion. It was wonderful that such

a poor, and weak, and slender thread as the bishop's life, should be spun out to such an amazing length. In the autumn of 1781 (usually the most favourable part of the year to him) he laboured under repeated illnesses; and on Saturday the 9th of February 1782, he began to find his breath much affected by the frost. His complaints grew worse and worse till the Thursday following. He got up at five o'clock, and was placed in a chair by the fire; complained to his wife how much he had suffered in bed, and repeated to himself that portion of the Psalms, "O my God, I cry unto thee in the day-time," &c. &c. About six o'clock he was left by his apothecary in a quiet sleep. Between seven and eight he awoke, and appeared rather more easy, and took a little refreshment. He continued dozing till near nine, when he ordered his servant to come and dress him, and help him down stairs. As soon as he was dressed, he inquired the hour, and bid his servant open the shutter and look at the dial of St Paul's. The servant answered, it was upon the stroke of nine. The bishop made an effort to take out his watch, with an intent to set it; but sunk down in his chair, and expired without a sigh, or the least visible emotion, his countenance still retaining the same placid appearance which was so peculiar to him when alive.

NIDDUI, in the Jewish customs, is used to signify "separated or excommunicated." This, according to some, was to be understood of the lesser sort of excommunication in use among the Hebrews. He that had incurred it was to withdraw himself from his relations, at least to the distance of four cubits: it commonly continued a month. If it was not taken off in that time, it might be prolonged for 60 or even 90 days: but if, within this term, the excommunicated person did not give satisfaction, he fell into the *cherem*, which was a second sort of excommunication; and thence into the third sort called *shammata*, or *shematta*, the most terrible of all. But Selden has proved that there were only two kinds of excommunication, viz. the greater and less; and that these three terms were used indifferently.

O.

ODIN, in mythology, called also in the dialect of the Anglo-Saxons *Woden* or *Wodan*, a name given by the ancient Scythians to their supreme god, and assumed, about 70 years before the Christian æra, by Sigge, a Scythian prince, who conquered the northern nations, made great changes in their government, manners, and religion, enjoyed great honours, and had even divine honours paid him. According to the account given of this conqueror by Snorro, the ancient historian of Norway, and his commentator Torfaus, Odin was a Scythian, who withdrew himself, with many others in his train, by flight, from the vengeance of the Romans, under the conduct of Pompey; and having officiated as priest in his own country, he assumed the direction of the religious worship, as well as

the civil government, of the nations which he conquered. Having subdued Denmark, Sweden, and Norway, he retired to Sweden, where he died. There is nothing certain in this account; but it is probable, that the god, whose prophet or priest this Scythian pretended to be, was named *Odin*, and that the ignorance of succeeding ages confounded the Deity with his priest, composing out of the attributes of the one, and the history of the other, the character of the northern conqueror. He deluded the people by his enchantments and skill in magic: having cut off the head of one Mimer, who in his lifetime was in great reputation for wisdom, he caused it to be embalmed, and persuaded the Scandinavians that he had restored it to the use of speech; and he caused it to pronounce what-

Oestrus
||
Palmæ.

ever oracles he wanted. The Icelandic chronicles represent Odin as the most eloquent and persuasive of men; they ascribe to him the introduction of the art of poetry among the Scandinavians, and likewise the invention of the Runic characters. He had also the address to persuade his followers, that he could run over the world in the twinkling of an eye; that he had the direction of the air and tempests; that he could transform himself into all sorts of shapes, could raise the dead, could forestall things to come, deprive his enemies, by enchantment, of health and vigour, and discover all the treasures concealed in the earth. They add, that by his tender and melodious airs, he could make the plains and mountains open and expand with delight; and that the ghosts, thus attracted, would leave their infernal caverns, and stand motionless about him. Nor was he less dreadful and furious in battle; changing himself into the shape of a bear, a wild bull, or a lion, and amidst ranks of enemies committing the most horrible devastation, without receiving any wound himself.

ŒSTRUS, (Enycl.) See Plate CCCXXII.—This is one of the most curious genera of insects. They are distinguished into several species, by reason of the different places wherein they deposit their eggs. Some, instructed by nature that their eggs cannot be hatched but under the skins of living creatures, such as bulls, cows, rein-deer, stags and camels, fix upon them at the instant of laying their eggs. From the hinder-part of their body issues a whimble of wonderful structure. It is a scaly cylinder, composed of four tubes, which draw out like the pieces of a spying-glass; the last is armed with three hooks, and is the gimblet with which the œstri bore through the tough hides of horned cattle. The animal seems to experience no pain from the puncture, unless the insect, plunging too deep, attacks some nervous fibre; in which case, the beast runs about, and becomes furious. The egg being hatched, the grub feeds on the matter of the wound. The place of its abode forms upon the body of the quadrupeds a bunch sometimes above an inch high. When full-grown, the larva breaks through the tumor, and slides down to the ground; for doing which it takes the cool of the morning, that it may neither be overpowered by the heat of the day, nor chilled by the cold of the night: it then digs itself a burrow, into which it retires. Its skin grows hard, and turns to a very solid shell. There it is transformed to a chrysalis, and afterwards to a winged insect. Nature has provided for every exigence: the shell wherein the œstrus is inclosed, is of so strong a texture that it could not make its way out, if at one of the ends there were not a small valve, fastened only by a very slight filament. The first push the œstrus makes, the door gives way, the prison opens. The insect wings its way to woods and places frequented by cattle. See **OESTRUS**, and **BOTTS, (Enycl.)**

ONONIS, RESTHARROW; a genus of the decandria order, belonging to the diadelphia class of plants. There are a number of different species; but the most

remarkable is the arvensis or cammock, growing in barren pastures in several parts of Scotland and England. The stalks recline towards the ground; are tough and branched, and have a red hairy bark. The flowers are red, and come out from the alze of the branches. As the plant grows old, the branches are all terminated by a sharp woody spine; in which state several authors, among whom is Dr Withering, have described it as a distinct species. The smooth sort is sometimes pickled as samphire. The whole plant is diuretic, and has been recommended in cases of jaundice and gravel. The plant abounds in Palestine; whence Mr Hasselquist conjectures (very probably according to Mr Lightfoot) that it is the thorn mentioned in the Scripture which the ground produced after the curse.

OPERA. For POETRY, chap. i. read POETRY, Part II. chap. ii.

OPORTO, or PORTO; a rich, handsome, and considerable town of Portugal, in the province of Entre Douro and Minho, with a bishop's see. It is a place of great importance, and by nature almost impregnable. It is noted for its strong wines; and a large quantity is from thence exported into Britain, whence all red wines that come from Spain or Portugal are called *port-wines*. It is seated on the declivity of a mountain near the river Douro, which forms an excellent harbour. W. Long. 8. 1. N. Lat. 41. 0.

OPPENHEIM, a town of Germany, in the lower palatinate of the Rhine, and capital of a bailiwick of the same name; seated on the declivity of a hill near the Rhine. E. Long. 8. 20. N. Lat. 49. 48.

OPTION, the power or faculty of wishing or choosing, or the choice a person makes of any thing.

When a new suffragan bishop is consecrated, the archbishop of the province, by a customary prerogative, claims the collation of the first vacant benefice or dignity in that see, according as he shall choose; which choice is called the *archbishop's option*.

But in case the bishop dies, or is translated before the present incumbent of the promotion chosen by the archbishop shall die or be removed, it is generally supposed that the option is void; inasmuch as the greater, singly and by himself, could not convey any right or title beyond the term of his continuance in that see. And if the archbishop dies before the avoidance shall happen, the right of filling up the vacancy shall go to his executors or administrators.

OSMUNDA, MOONWORT, a genus of the order of filices, belonging to the cryptogamia class of plants. There are several species; the most remarkable of which is the regalis, osmund-royal, or flowering-fern. This is a native of Britain, growing in putrid marshes. Its leaf is doubly winged, bearing bunches of flowers at the ends. The root boiled in water is very slimy; and is used in the north to stiffen linen instead of starch. Only some of the leaves bear flowers.

OTALGIA, (Enycl.) Instead of, "See there, n° 314. and p. 4869." read, See **EAR-ACH**, in **APPENDIX**.

P.

PAINTER'S BALANCE. See **PAINTING**, n° 18.
PALMÆ, PALMS. Under this name Linnæus has

arranged several genera, which, although capable of a place in separate classes of his system, he has chosen rather,

Opera
||
Otalgia.

rather, on account of their singular structure, to place apart, in an appendix to the work.—See *ARECA*, *CHAMEROPS*, *PHOENIX*, *COCOS*, &c. (*Encycl.*); and *CORYPHA*, in this APPENDIX.

The same plants constitute one of the seven families or tribes into which all vegetables are distributed by Linnæus in his *Philosophia Botanica*. They are defined to be plants with simple stems, which at their summit bear leaves resembling those of the ferns, being a composition of a leaf and a branch; and whose flowers and fruit are produced on that particular receptacle or seat called a *spadix*, protruded from a common calyx in form of a sheath or scabbard, termed by Linnæus *spatha*.

Palme is likewise the name of the first order in Linnæus's *Fragments of a Natural Method*. See *BOTANY*, p. 1304.

PANAX, (*Encycl.*) See Plate CCCXXII.

PARONYCHIA, the *WHITLOW*, in surgery, is an abscess at the end of the fingers. According as it is situated more or less deep, it is differently denominated, and divided into species.

It begins with a slow heavy pain, attended with a slight pulsation, without swelling, redness, or heat; but soon the pain, heat, and throbbing, are intolerable; the part grows large and red, the adjoining fingers and the whole hand swell up; in some cases, a kind of red and inflated streak may be observed, which beginning at the affected part, is continued almost to the elbow; nor is it unusual for the patient to complain of a very sharp pain under the shoulder, and sometimes the whole arm is excessively inflamed and swelled; the patient cannot sleep, the fever, &c. increasing; and sometimes delirium or convulsions follow.

1. When it is seated in the skin or fat, in the back or the fore part of the finger, or under or near the nail, the pain is severe, but ends well. 2. When the periosteum is inflamed or corroded, the pain is tormenting. 3. When the nervous coats of the flexor tendons of the fingers or nerves near them are seized, the worst symptoms attend. If the first kind suppurates, it must be opened, and treated as abscesses in general; but the best method of treating the other two species is, on the first, or at furthest the second day, to cut the part where the pain is seated quite to the bone; if this operation is longer deferred, a suppuration will come on; in which case suppuration should be speedily promoted, and as early a discharge given to the matter as possible. As the pain is so considerable as to occasion a fever, and sometimes convulsions, the tinct. theb. may be added to the suppurating applications, and also given in a draught at bed-time. The second species proves very troublesome, and sometimes ends in a caries of the subjacent bone. The third species is very tedious in the cure, and usually the phalanx on which it is seated, is destroyed.

PARMESAN CHEESE, a sort of cheese much esteemed among the Italians; so named from the duchy of Parma where it is made, and whence it is conveyed to various parts of Europe.

The excellent pasture-grounds of this country are watered by the Po; and the cows from whose milk this cheese is made yield a great quantity of it. Of this cheese there are three sorts; the *fromaggio di for-*

ma, about two palms in diameter, and seven or eight inches thick; and the *fromaggio di ribbole* and *di ribolini*, which are not so large. This cheese is of a sallow-colour; and the best is kept three or four years.

PARRA, in ornithology, a genus of birds belonging to the order of grallæ; the characters of which are: The bill is tapering and a little obtuse; the nostrils are oval, and situated in the middle of the bill; the forehead is covered with fleshy caruncles, which are lobated; the wings are small, and spinous. There are five species; of which the most remarkable is the chavaria, which is about the size of the domestic cock. The Indians in the neighbourhood of Carthage, who breed large flocks of poultry that stray in the woods, train up the chavaria to defend them against the numerous birds of prey, no one of which will dare to encounter it. It is never known to desert the flock, and it returns every evening to roost.

PARTING, in chemistry, an operation by which gold and silver are separated from each other. As these two metals resist equally well the action of fire and of lead, they must therefore be separated by other methods. This separation could not be effected if they were not soluble by different menstrua.

Nitrous acid, marine acid, and sulphur, which cannot dissolve gold, attack silver very easily; and therefore these three agents furnish methods of separating silver from gold, or of the operation called *parting*.

Parting by nitrous acid is the most convenient, and therefore most used, and even almost the only one employed by goldsmiths and coiners. Wherefore it is called simply *parting*. That made with the marine acid is only made by cementation, and is known by the name of *concentrated parting*. Lastly, parting by sulphur is made by fusion, which the chemists call the *dry way*, and is therefore called *dry parting*.

PARTING by Aquafortis. Although parting by aquafortis be easy, as we have said, it cannot however succeed or be very exact, unless we attend to some essential circumstances.

1. The gold and silver must be in a proper proportion; for if the gold was in too great quantity, the silver would be covered and guarded by it from the action of the acid.

Therefore, when essayers do not know the proportion of these two metals in the mass to be operated upon, they discover it by the following method.

They have a certain number of needles composed of gold and silver alloyed together in graduated proportions, and the alloy of each needle is known by a mark upon it. These are called *proof-needles*.

When essayers want to know nearly the proportion of gold and silver in a mass, they rub this mass upon a touchstone, so as to leave a mark upon it. They then make marks upon the touchstone with some of the needles the colour of which they think comes nearest to that of the mass. By comparing the marks of these needles with the mark of the mass, they discover nearly the proportion of the gold and silver in the mass.

If this trial shows, that in any given mass the silver is not to the gold as three to one, this mass is improper for the operation of parting by aquafortis. In this case, the quantity of silver necessary to make an alloy of that proportion must be added.

This operation is called *quartation*, probably because

Parting. it reduces the gold to a fourth part of the whole mafs.

2. That the parting may be exact, the nitrous acid or aquafortis employed muft be very pure, and efpecially free from mixture of vitriolic and marine acids. For if this was not attended to, a quantity of filver, proportionable to thefe two foreign acids would be feparated during the folution; and this portion of filver reduced by thefe acids to vitriol of filver and to luna cornea, would remain mingled with the gold, which confequently would not be entirely purified by the operation.

When the metallic mafs is properly allayed, it is to be reduced to plates, rolled up fpirally, called cornets; or to grains. There are to be put into a matrafs, and upon them a quantity of aquafortis is to be poured, the weight of which is to that of the filver as three to two: and as the nitrous acid employed for this operation is rather weak, the folution is affifted, efpecially at firft, by the heat of a fand-bath, in which the matrafs is to be placed. When, notwithstanding the heat, no further mark of folution appears, the aquafortis charged with filver is to be decanted. Frefh nitrous acid is to be poured into the matrafs, ftronger than the former, and in lefs quantity, which muft be boiled on the refiduous mafs, and decanted as the former. Aquafortis muft even be boiled a third time on the remaining gold, that all the filver may be certainly diffolved. The gold is then to be wafhed with boiling water. This gold is very pure, if the operation has been performed with due attention. It is called *gold of parting*.

No addition of filver is required, if the quantity of filver of the mafs is evidently much more confiderable than that of the gold: perfons who have not proof needles and other apparatus to determine the proportion of the alloy, may add to the gold an indeterminate quantity of filver, obferving that this quantity be rather too great than too fmall, and fo confiderable as to render the mafs nearly as white as filver; for a large quantity of filver is rather favourable than hurtful to the operation: It has no other inconvenience than an ufelefs expence, as the larger the quantity is of filver, the more aquafortis muft be employed. We ought to attend to this fact, that the colour of gold is fcarcely perceptible in a mafs two-thirds of which is filver and one-third is gold; this colour then muft be much lefs perceptible when the gold is only one-fourth part, or lefs, of the whole mafs.

If the quantity of gold exceeds that of the filver, the mafs may be expofed to the action of aquaregia, which would be a kind of inverfe parting, becaufe the gold is diffolved in that menftruum, and the filver is not, but rather reduced to a luna cornea, which remains in form of a precipitate after the operation. But this method is not much praftised, for the following reafons.

First, the gold cannot be eafily feparated from the aquaregia; for if the parting has been made with an aquaregia prepared with fal ammoniac, or if the gold be precipitated by a volatile alkali, this gold has a fulminating quality, and its reduction requires particular operations. If the aquaregia has been made with fpirit of falt, and the precipitation effected by a fixed alkali, the gold will not then be fulminating, but the precipitation will be very flow, and probably incomplete.

Secondly, in the parting by aquaregia, the filver is indeed precipitated into a luna cornea, and thus feparated; but this feparation is not perfect, as a fmall quantity of luna cornea will always remain diffolved by the acids, if this folution even could be only effected by the fuperabundant water of thefe acids. Accordingly the filver is not fo accurately feparated from the gold by aquaregia, as the gold is from the filver by aquafortis.

The gold, after the parting by aquafortis, is much more eafily collected when it remains in fmall mafles, than when it is reduced to a powder.

When the mafs has been regularly parted, that is, when it contains three parts of filver and one part of gold, we muft employ, particularly for the firft folution, an aquafortis fo weakened that heat is required to affift the folution of the filver: by which means the folution is made gently; and the gold which remains, preserves the form of the fmall mafles before the folution. If the aquafortis employed were ftronger, the parts of the gold would be difuniting and reduced to the form of a powder, from the activity with which the folution would be made.

We may indeed part by aquafortis a mafs containing two parts of filver to one part of gold: but then the aquafortis muft be ftronger; and if the folution be not too much haftened, the gold will more eafily remain in mafles after the operation. In both cafes, the gold will be found to be tarnifhed and blackened, probably from the phlogifton of the nitrous acid. Its parts have no adhefion together, becaufe the filver diffolved from it has left many interftices; and the cornets or grains of this gold will be eafily broken, unlefs they be handled very carefully. To give them more folidity, they are generally put into a telt under a muffle and made red-hot, during which operation they contract confiderably, and their parts are approximated. Thefe pieces of gold are then found to be rendered much more folid, fo that they may be handled without being broken. By this operation alfo the gold refumes its colour and luftre; and as it generally has the figure of cornets, it is called *gold in cornets*, or *grain gold*. Effayers avoid melting it, as they chofe to preserve this form, which fhows that it has been parted.

The gold and filver thus operated upon ought to have been previously refined by lead, and freed from all alloy of other metallic matters, fo that the gold which remains fhould be as pure as is poffible. However, as this is the only metal which refifts the action of aquafortis, it might be purified by parting from all other metallic fubftances; but this is not generally done, for feveral reafons. Firft, becaufe the refining by lead is more expeditious and convenient for the feparation of the gold from the imperfect metals; fecondly, becaufe the filver, when afterwards feparated from the aquafortis, is pure; laftly, becaufe moft imperfect metals do not remain completely and entirely diffolved in nitrous acid, from the portion of phlogifton which this acid deprives them of, the gold would be found after the parting mixed with the part of thefe metals which is precipitated.

The gold remaining after the parting ought to be well wafhed, to cleanfe it from any of the folution of filver which might adhere to it; and for this purpofe diffil-

led

led water ought to be used, or at least water the purity of which has been ascertained by its not forming a precipitate with a solution of silver, because such a precipitate would alter the purity of the gold.

The silver dissolved in the aquafortis may be separated either by distillation, in which case all the aquafortis is recovered very pure, and fit for another parting; or it may be precipitated by some substance which has a greater affinity than this metal with nitrous acid. Copper is generally employed for this purpose at the mint.

The solution of silver is put into copper vessels. The aquafortis dissolves the copper, and the silver precipitates. When the silver is all precipitated, the new solution is decanted, which is then a solution of copper. The precipitate is to be well washed, and may be melted into an ingot. It is called *parted silver*. When this silver has been obtained from a mass which had been refined by lead, and when it has been well washed from the solution of copper, it is very pure.

Mr Cramer observes justly in his Treatise on Essaying, that however accurately the operation of parting has been performed, a small portion of silver always remains united with the gold, if the parting has been made by aquafortis; or a small portion of the gold remains united with the silver, if the parting has been made by aquaregia; and he estimates this small alloy to be from a two hundredth to a hundredth and fiftieth part; which quantity may be considered as nothing for ordinary purposes, but may become sensible in accurate chemical experiments. *Chem. Dict.*

The mass of gold and silver to be parted, ought previously to be granulated; which may be done by melting it in a crucible, and pouring it into a large vessel full of cold water, while at the same time a rapid circular motion is given to the water by quickly stirring it round with a stick or broom.

The vessels generally used for this operation, called *parting-glasses*, have the form of truncated cones, the bottom being commonly about seven inches wide, the aperture about one or two inches wide, and the height about 12 inches. These glass-vessels ought to have been well annealed, and chosen free from flaws; as one of the chief inconveniences attending the operation is, that the glasses are apt to crack by exposure to cold, and even when touched by the hand. Some operators secure their glasses by a coating. For this purpose they spread a mixture of quicklime slaked with beer and whites of eggs upon linen cloth, which they wrap round the lower part of the vessel, leaving the upper part uncovered, that they may see the progress of the operation; and over this cloth they apply a composition of clay and hair. Schlutter advises to put the parting-glasses containing some water, and supported by trestle, with fire under them. When the heat communicated by the water is too great, it may be diminished by adding cold water, which must be done very carefully by pouring against the sides of the pan, to prevent too sudden an application of cold to the parting-glass. The intention of this contrivance is, that the contents of the glasses, if these should break, may be received by the copper vessel. Into a glass 15 inches high, and 10 or 12 inches wide at bottom, placed in a copper-pan 12 inches wide at bottom, 15 inches wide at top, and 10 inches high, he usually put about 80 ounces of metal, with twice as

Vol. X.

much aquafortis.

The aquafortis ought to be so strong as to be capable of acting sensibly on silver when cold, but not so strong as to act violently. If the aquafortis be very strong, however pure, and if the vessels be well closed, a small quantity of the gold will be dissolved along with the silver, which is to be guarded against.

Little heat ought to be applied at the beginning, the liquor being apt to swell and rise over the vessel; but when the acid is nearly saturated, the heat may be safely encreased.

When the solution ceases, which may be known by the discontinuance of the effervescence, or emission of air-bubbles, the liquor is to be poured off. If any grains appear entire, more aquafortis must be added, that all the silver may be dissolved. If the operation has been performed slowly, the remaining gold will have still the form of distinct masses, which are to receive solidity and colour by fire, in the manner directed by the author of the Dictionary. If the operation has been performed hastily, the gold will have the appearance of a black mud or powder, which after five or six washings with pure water must be melted.

The silver is usually recovered by precipitating it from the aquafortis by means of copper-vessels into which the liquor is poured, or of plates of copper which are thrown along with the liquor into glass-vessels. A considerable heat is required to accelerate this precipitation. Dr Lewis says, he has observed that when the aquafortis was perfectly saturated with silver, no precipitation was occasioned by plates of copper, till a drop or two of aquafortis was added to the liquor, and then the precipitation began and continued as usual.

The precipitated silver must be well washed in boiling water, and fused with some nitre; the use of which is to scoriify any cupreous particles, which may adhere to the silver.

From the solution of copper in aquafortis, a blue pigment, called *verditer*, is obtained by precipitation with whiting. *Notes to Chem. Dict.*

Concentrated PARTING, also called *Parting by Cementation*, because it is actually performed by cementation, is used when the quantity of it is so great in proportion to the silver, that it cannot be separated by aquafortis. This operation is done in the following manner.

A cement is first prepared, composed of four parts of bricks powdered and sifted, of one part of green vitriol calcined till it becomes red, and of one part of common salt. The whole is very accurately mixed together, and a firm paste is made of it by moistening it with a little water or urine. This cement is called *cement royal*, because it is employed to purify gold, which is considered by chemists as the king of metals.

The gold to be cemented is to be reduced to plates as thin as small pieces of money. At the bottom of the crucible or cementing-pot, a stratum of cement, of the thickness of a finger, is to be put, which is to be covered with plates of gold; upon these another stratum of cement is to be laid; and then more plates of gold, till the crucible or pot is filled with these alternate strata of cement and of gold. The whole is then to be covered with a lid, which is to be luted with a mixture of clay and sand. This pot is to be placed

in a furnace, or oven, and heated by degrees till it is moderately red, which heat is to be continued during 24 hours. The heat must not be so great as to melt the gold. The pot or crucible is then left to cool, and the gold is to be carefully separated from the cement, and boiled at different times in a large quantity of pure water. This gold is to be elayed upon a touchstone or otherwise; and if it be found not sufficiently purified, it is to be cemented a second time in the same manner.

The vitriolic acid of the bricks and of the calcined vitriol disengages the acid of the common salt during this cementation: and this latter acid dissolves the silver allayed with the gold, and separates it by that means.

This experiment proves, that although marine acid, while it is liquid, cannot attack silver, it is nevertheless a powerful solvent of that metal. But for this purpose it must be applied to the silver in the state of vapours, extremely concentrated, and assisted with a considerable heat. All these circumstances are united in the concentrated parting.

This experiment proves also, that notwithstanding all these circumstances, which favour the action of the marine acid, it is incapable of dissolving gold.

Lastly, the marine acid in this state more effectually dissolves the silver than the nitrous acid does in the parting by aquafortis, since this operation succeeds well when the silver is in so small a proportion as that it would be protected from the action of the nitrous acid in the ordinary parting.

Instead of sea-salt, nitre may be used with equal success; because the nitrous acid is then put in a state to attack the silver, notwithstanding the quantity of gold which covers it.

Dry Parting. Dry parting, or parting by fusion, is performed by sulphur, which has the property of uniting easily with silver, while it does not attack gold.

This method of separating these two metals would be the cheapest, the most expeditious and convenient of any, if the sulphur could dissolve the silver, and separate it from the gold as well and as easily as nitrous acid does: but, on the contrary, we are obliged to employ particular treatment, and a kind of concentration, to begin the union of the sulphur allayed with gold. Then repeated and troublesome fusions must be made, in each of which we are obliged to add different intermediate substances, and particularly the metals which have the strongest affinity with sulphur, to assist the precipitation, which in that case does not give a regulus of pure gold, but a gold still allayed with much silver, and even with a part of the precipitating metals; so that, to complete the operation, cupellation is necessary, and also parting by aquafortis.

From what we have said concerning this operation, we may perceive, that it ought not to be made but when the quantity of silver with which the gold is allayed is so great, that the quantity of gold which might be obtained by the ordinary parting is not sufficient to pay the expences; and that it is only proper for concentrating a larger quantity of gold in a smaller quantity of silver. As this dry parting is troublesome, and even expensive, it ought not to be undertaken but on a considerable quantity of silver allayed with gold. Accordingly Cramer, Schlutter, Schlinder, and all good

chemists and artists who have given processes for the dry parting, recommend its use only in the abovementioned cases. We wish that this operation could be improved: it would be much more advantageous if it could be done by two or three fusions; and if by these an exact separation could be obtained of a small quantity of gold mixed with a large quantity of silver.

Chem. Dict.

As this operation for extracting a small quantity of gold from a large quantity of silver is, notwithstanding its inconveniences, approved by Schlutter, Scheffer, and other authors, and practised in Hartz, we shall add what Dr Lewis, in his excellent History of Gold, has said upon the subject.

The most advantageous method of separating a small portion of gold from a large one of silver, appears to be by means of sulphur, which unites with and scorifies the silver without affecting the gold: but as sulphurated silver does not flow thin enough to suffer the small particles of gold diffused through it to reunite and settle at the bottom, some addition is necessary for collecting and carrying them down.

In order to the commixture with the sulphur, 50 or 60 pounds of the mixed metal, or as much as a large crucible will receive, are melted at once, and reduced into grains, by lading out the fluid matter, with a small crucible made red-hot, and pouring it into cold water stirred with a rapid circular motion. From an eighth to a fifth of the granulated metal, according as it is richer or poorer in gold, is reserved, and the rest well mingled with an eighth of powdered sulphur. The grains enveloped with the sulphur are again put into the crucible, and the fire kept gentle for some time, that the silver, before it melts, may be thoroughly penetrated by the sulphur; if the fire was hastily urged, great part of the sulphur would be dissipated, without acting upon the metal.

If to sulphurated silver in fusion pure silver be added, the latter falls to the bottom, and forms there a distinct fluid not miscible with the other. The particles of gold, having no affinity with the sulphurated silver, join themselves to the pure silver, wherever they come in contact with it, and are thus transferred from the former into the latter, more or less perfectly according as the pure silver was more or less thoroughly diffused through the mixed. It is for this use that a part of the granulated metal was reserved. The sulphurated mass being brought into perfect fusion, and kept melted for near an hour in a close covered crucible, one-third of the reserved grains is thrown in; and as soon as this is melted, the whole is well stirred, that the fresh silver may be distributed through the mixed, to collect the gold from it. The stirring is performed with a wooden rod; an iron one would be corroded by the sulphur, so as to deprive the mixed of its due quantity of sulphur, and likewise render the subsequent purification of the silver more troublesome. The fusion being continued an hour longer, another third of the unsulphurated grains is added, and an hour after this the remainder; after which the fusion is further continued for some time, the matter being stirred at least every half hour from the beginning to the end, and the crucible kept closely covered in the intervals.

The sulphurated silver appears in fusion of a dark-brown

ing. brown colour: after it has been kept melted for a certain time, a part of the sulphur having escaped from the top, the surface becomes white, and some bright drops of silver, about the size of pease, are perceived on it. When this happens, which is commonly in about three hours after the last addition of the reserved grains, sooner or later according as the crucible has been more or less closely covered, and the matter more or less stirred, the fire must be immediately discontinued; for otherwise more and more of the silver, thus losing its sulphur, would subside and mingle with the gold at the bottom in which the gold is collected. The whole is poured out into an iron mortar greased and duly heated; or if the quantity is too large to be safely lifted at once, a part is first laded out from the top with a small crucible, and the rest poured into the mortar. The gold, diffused at first through the whole mass, is now found collected into a part of it at the bottom, amounting only to about as much as was reserved unsulphurated. This part may be separated from the sulphurated silver above it by a chisel and hammer; or more perfectly, the surface of the lower mass being generally rugged and unequal, by placing the whole mass with its bottom upwards in a crucible: the sulphurated part quickly melts, leaving unmelted that which contains the gold, which may thus be completely separated from the other. The sulphurated silver is essayed by keeping a portion of it in fusion in an open crucible till the sulphur is dissipated, and then dissolving it in aquafortis. If it should still be found to contain any gold, it is to be melted again; as much more unsulphurated silver is to be added as was employed in each of the former injections, and the fusion continued about an hour and a half.

The gold thus collected into a part of the silver may be further concentrated into a smaller part, by granulating the mass and repeating the whole process. The operation may be again and again repeated, till so much of the silver is separated, that the remainder may be parted by aquafortis without too much expence.

The foregoing process, according to Mr Schlutter, is practised at Rammelsberg in the Lower Hartz. The prevailing metal in the ore of Rammelsberg is lead: the quantity of lead is at most 40 pounds on a quintal or 100 pounds of the ore. The lead worked off on a test or concave hearth yields about 110 grains of silver, and the silver contains only a 384th part of gold; yet this little quantity of gold, amounting scarcely to a third of a grain in a hundred weight of this ore, is thus collected with profit. The author abovementioned confines this method of separation to such silver as is poor in gold, and reckons parting with aquafortis more advantageous where the gold amounts to above a 64th of the silver: he advises also not to attempt concentrating the gold too far, as a portion of it will always be taken up again by the silver. Mr Scheffer, however, relates, (in the Swedish Memoirs for the year 1752), that he has by this method brought the gold to perfect fineness; and that he has likewise collected all the gold which the silver contained; the silver of the last operations, which had taken up a portion of the gold, being reserved to be worked over again with a fresh quantity of gold-holding silver. The sulphurated silver is purified by continuing it in

fusion for some time with a large surface exposed to the air; the sulphur gradually exhales, and leaves the silver entire.

PASSIFLORA, or PASSION-FLOWER, a genus of the pentandria order, belonging to the gynandria class of plants. There are near 30 different species; all of them natives of warm foreign countries, only one of which is sufficiently hardy to succeed well in the open ground here; all the others requiring the shelter of a green-house or stove, but chiefly the latter. The most remarkable are,

1. The *cærulea*, or blue-rayed common palmated passion-flower, hath long, slender, shrubby, purplish-green stalks, branchy, and ascending upon support by their claspers thirty or forty feet high; with one large palmated leaf at each joint, and at the axillas large spreading flowers, with whitish-green petals, and a blue radiated nectarium; succeeded by a large, oval, yellowish fruit. It flowers from July until October; the flowers are very large, conspicuous, and their composition is exceedingly curious and beautiful. The general structure of the singular flowers of this plant is, they come out at the axillas on pedunculi about three inches long, which they terminate, each flower having just close under the calix a three-lobed involucre-like appendage; a five-lobed calix, and a five-petalous corolla, the size, figure, and colour of the calix, &c. the petals arranging alternately with the calicinal lobes; the whole, including the involucre, calix, and corolla, make just 13 lobes and petals, all expanded flat: and within the corolla is the nectarium, composed of a multitude of thread-like fibres, of a blue and purple colour, disposed in circular rays round the column of the fructification; the outer ray is the longest, flat, and spreading on the petals; the inner is short, erect, and narrows towards the centre: in the middle is an erect cylindric club-shaped column, or pillar, crowned with the roundish germen, having at its base five horizontal spreading filaments, crowned with incumbent yellow anthers, that move about every way; and from the side of the germen arise three slender spreading styles, terminated by headed stigmas: the germen afterwards gradually becomes a large oval fleshy fruit, ripening to a yellowish colour.—These wonderful flowers are only of one day's duration, generally opening about 11 or 12 o'clock, and frequently in hot sunny weather burst open with elasticity, and continue fully expanded all that day; and the next they gradually close, assuming a decayed-like appearance, and never open any more; the evening puts a period to their existence, but they are succeeded by new ones daily on the same plant.—This plant and flowers are held in great veneration in some foreign Catholic countries, where the religious make the leaves, tendrils, and different parts of the flower, to represent the instruments of our blessed Saviour's passion; hence the name *passiflora*.

2. The *incarnata*, incarnated, or flesh-coloured Italian passion-flower, hath a strong perennial root; slender, herbaceous stalks, rising upon support four or five feet high; leaves composed of three sawed lobes, each leaf attended by a twining tendril; and at the axillas long slender pedunculi, terminated each by one whitish flower, having a greenish calix, and a reddish or purple radiated nectarium, surrounding the column of the

fructification, which succeed to a large, round, fleshy fruit, ripening to a beautiful orange colour.—The flowers of this species are also very beautiful, though of short duration, opening in the morning, and night puts a period to their beauty; but they are succeeded by a daily supply of new ones.—The fruit of this sort is also very ornamental, as ripening to a fine reddish orange colour; but these rarely attain perfection here, unless the plants are placed in the stove; therefore when there is such accommodation, it highly merits that indulgence, where it will exhibit both flowers and green and ripe fruit, all at the same time, in a beautiful manner.

3. The *vespertilio*, or bat's-wing passion-flower, hath slender, striated, branchy stalks; large, bilobate, or two-lobed leaves, the base roundish and glandular, the lobes acute, widely divaricated like a bat's wings, and dotted underneath; and axillary flowers, having white petals and rays. The leaves of this species have a singular appearance, the two lobes being expanded six or seven inches wide, resembling the wings of a bat upon flight; hence the name *vespertilio*.

As all the species are natives of warm climates, in this country they are mostly of a tender quality, except the first sort, which succeeds very well in the full ground, in a warm situation; only their young branches are sometimes killed in very severe winters; but plenty of new ones generally rise again in spring following: the others, denominated *stove* kinds, must always be retained in that repository.

PAWN, a pledge or gage for surety of payment of money lent. It is said to be derived a *pugno, quia res quæ pignori dantur, pugno vel manu traduntur*. The party that pawns goods hath a general property in them; they cannot be forfeited by the party that hath them in pawn for any offence of his, nor be taken in execution for his debt; neither may they otherwise be put in execution till the debt for which they are pawned is satisfied.

If the pawn is laid up, and the pawnee robbed, he is not answerable; though if the pawnee use the thing, as a jewel, watch, &c. that will not be the worse for wearing, which he may do, it is at his peril; and if he is robbed, he is answerable to the owner, as the using occasioned the loss, &c.

If the pawn is of such a nature that the keeping is a charge to the pawnee, as a cow, or a horse, &c. he may milk the one, and ride the other, and this shall go in recompence for his keeping.

Things which will grow the worse by using, as apparel, &c. he may not use.

PAVING, the construction of ground-floors, streets, or high-ways, in such a manner that they may be conveniently walked upon. In Britain, the pavement of the grand streets, &c. are usually of flint, or rubble-stone; courts, stables, kitchens, halls, churches, &c. are paved with tiles, bricks, flags, or fire-stone; sometimes with a kind of free-stone, and rag-stone.

In some streets, *e. gr.* of Venice, the pavement is of brick; churches sometimes are paved with marble, and sometimes with mosaic work, as the church of St Mark at Venice. In France, the public roads, streets, courts, &c. are all paved with gres or gritt, a kind of free-stone.

In Amsterdam and the chief cities of Holland, they

call their brick pavement the *burgher-masters pavement*, to distinguish it from the stone or flint pavement, which usually takes up the middle of the street, and which serves for carriages; the brick which borders it being destined for the passage of people on foot.

Pavements of free-stone, flint, and flags, in streets, &c. are laid dry, *i. e.* in a bed of sand; those of courts, stables, ground rooms, &c. are laid in a mortar of lime and sand; or in lime and cement, especially if there be vaults or cellars underneath. Some masons, after laying a floor dry, especially of brick, spread a thin mortar over it; sweeping it backwards and forwards to fill up the joints. The several kinds of pavement are as various as the materials of which they are composed, and whence they derive the name by which they are distinguished; as,

1. *Pebble-paving*, which is done with stones collected from the sea-beach, mostly brought from the islands of Guernsey and Jersey; they are very durable, indeed the most so of any stone used for this purpose. They are used of various sizes, but those which are from six to nine inches deep, are esteemed the most serviceable. When they are about three inches deep, they are denominated *bolders*, or *bowlers*; these are used for paving court-yards, and other places not accustomed to receive carriages with heavy weights; when laid in geometrical figures, they have a very pleasing appearance.

2. *Rag-paving* was much used in London, but is very inferior to the pebbles; it is dug in the vicinity of Maidstone, in Kent, from which it has the name of *Kentish rag-stone*; there are squared stones of this material for paving coach-tracks and foot-ways.

3. *Purbeck pitchens*; square stones used in footways; they are brought from the island of Purbeck, and also frequently used in court-yards; they are in general from six to ten inches square, and about five inches deep.

4. *Squared paving*, for distinction by some called *Scotch paving*, because the first of the kind paved in the manner that has been and continues to be paved, came from Scotland; the first was a clear close stone, called *blue whyn*, which is now disused, because it has been found inferior to others since introduced in the order they are hereafter placed.

5. *Granite*, a hard material, brought also from Scotland, of a reddish colour, very superior to the blue whynn quarry.

6. *Guernsey*, which is the best, and now almost the only stone in use; it is the same stone with the pebble before spoken of, but broken with iron hammers, and squared to any dimensions required of a prismoidal figure, set with its smallest base downwards. The whole of the foregoing paving should be bedded and paved in small gravel.

7. *Purbeck-paving*, for footways, is in general got in large surfaces about 2½ inches thick; the blue fort is the hardest and the best of this kind of paving.

8. *Yorkshire paving*, is an exceeding good material for the same purpose, and is got of almost any dimensions of the same thickness as the Purbeck. This stone will not admit the wet to pass through it, nor is it affected by the frost.

9. *Ryegate, or fire-stone paving*, is used for hearths, stoves, ovens, and such places as are liable to great heat, which does not affect this stone if kept dry.

10. *Newcastle flags*, are stones about two feet square, and $1\frac{1}{2}$ or two inches thick; they answer very well for paving out-offices; they are somewhat like the Yorkshire.

11. *Portland paving*, with stone from the island of Portland; this is sometimes ornamented with black marble dots.

12. *Swedland paving*, is a black slate dug in Leicestershire, and looks well for paving halls, or in party-coloured paving.

13. *Marble paving*, is mostly variegated with different marbles, sometimes inlaid in mosaic.

14. *Flat brick paving*, done with brick laid in sand, mortar, or grout, as when liquid lime is poured into the joints.

15. *Brick-on-edge paving*, done with brick laid edgewise in the same manner.

16. Bricks are also laid flat or edgewise in herring-bone.

17. Bricks are also sometimes set endwise in sand, mortar, or grout.

18. Paving is also performed with paving bricks.

19. With ten inch tiles.

20. With foot tiles.

21. With clinkers for stables and outer offices.

22. With the bones of animals, or gardens, &c.

And, 23. We have knob-paving, with large gravel-stones, for porticoes, garden-seats, &c.

Pavements of churches, &c. frequently consist of stones of several colours; chiefly black and white, and of several forms, but chiefly squares and hexagons, artfully disposed. Indeed, there needs no great variety of colours to make a surprising diversity of figures and arrangements. M. Truchet, in the Memoir of the French Academy, has shown by the rules of combination, that two square-stones, divided diagonally into two colours, may be joined together chequerwise, 64 different ways; which appears surprising enough; see two letters, or figures, can only be combined two ways.

The reason is, that letters only change their situation with regard to the first and second, the top and bottom remaining the same; but in the arrangement of these stones, each admits of four several situations, in each whereof the other square may be changed 16 times, which gives 64 combinations.

Indeed, from a farther examination of these 64 combinations, he found there were only 32 different figures, each figure being repeated twice in the same situation, though in a different combination; so that the two only differed from each other by the transposition of the dark and light parts.

PERIAGUA, a sort of large canoe made use of in the Leeward islands, South America, and the gulf of Mexico. It is composed of the trunks of two trees, hollowed and united together; and thus differs from the Canoe which is formed of one tree.

PERSIMON (*Diospyros Virginiana*, Linn.) a tree pretty common in North America; the fruit of which, when ripe, is sweet and glutinous, with a little astringency. From the persimon is made a very palatable liquor, in the following manner. As soon as the fruit is ripe, a sufficient quantity is gathered, which is very easy, as each tree is well stocked with them. These persimon apples are put into a dough of wheat or other flour, formed into cakes, and put into an oven, in which they continue till they are quite baked and sufficiently dry, when they are taken out again; then,

in order to brew the liquor, a pot full of water is put on the fire, and some of the cakes are put in: these become soft by degrees as the water grows warm, and crumble in pieces at last; the pot is then taken from the fire, and the water in it well stirred about, that the cakes may mix with it; this is then poured into another vessel, and they continue to steep and break as many cakes as are necessary for a brewing: the malt is then infused, and they proceed as usual with the brewing. Beer thus prepared is reckoned much preferable to other beer. They likewise make brandy of this fruit in the following manner: having collected a sufficient quantity of persimons in autumn, they are all together put into a vessel, where they lie for a week till they are quite soft: then they pour water on them, and in that state they are left to ferment of themselves, without promoting the fermentation by any addition. The brandy is then made in the common way, and is said to be very good, especially if grapes (in particular of the sweet sort) which are wild in the woods, be mixed with the persimon fruit. Some persimons are ripe at the end of September, but most of them later, and some not before November and December, when the cold first overcomes their acrimony. The wood of this tree is very good for joiners instruments, such as planes, handles to chisels, &c. but if after being cut down it lies exposed to sunshine and rain, it is the first wood which rots, and in a year's time there is nothing left but what is useless. When the persimon trees get once into a field, they are not easily got out of it again, as they spread so much.

PEZIZA, *CUP-MUSHROOM*, in botany, a genus of the class of cryptogamia, and order of fungi. This mushroom is bell-shaped and sessile. Linnæus enumerates eight species.

PHAETON, in ornithology, a genus of birds belonging to the order of anseres; the characters of which are: The bill is sharp, straight, and pointed; the nostrils are oblong, and the hinder toe is turned forward. There are two species, viz.

1. The demersus, or penguin, has a thick, arched, and bill; the head, hind-part of the neck, and the back, of a dusky purplish hue, and breast and belly white; brown wings, with the tips of the feathers white; inside of a tail, a few black bristles; and red legs. It is found on Penguin isle, near the Cape of Good Hope.

2. The ethereus, or tropic bird, is about the size of a partridge, and has very long wings. The bill is red, with an angle under the lower mandible. The eyes are encircled with black, which ends in a point towards the back of the head. Three or four of the larger quills, towards their ends, are black, tipped with white; all the rest of the bird is white, except the back, which is variegated with curved lines of black. The legs and feet are of a vermilion red. The toes are webbed. The tail consists of two long straight narrow feathers, and a set of equal breadth from their quills to their point. See Plate CCCXXI. These birds are rarely seen but between the tropics, at the remotest distance from the equator. Their name seems to imply the limits of their residence; and although they are seldom seen but a few degrees north or south of either tropic, yet one of their breeding-places is almost nine degrees from the northern tropic, viz. at Bermudas. They breed also in great numbers on some little islands at the east end of Porto Rico.

PHARMACY, (*Encycl.*) n° 288. Correct thus :
 " Let the iron-filings be put below a lawn or gauze
 sieve, and the magnet applied above ; it will attract
 them through the pores of the sieve, and thus free them
 more effectually from heterogeneous matter."

PHASCUM, in botany, a genus of the class of cryptogamia, and order of musci or mosses. Its characters are, that the anthera is covered, and guarded at the margin by parallel bristles; and that the calyptra, or veil, is small. There are four species.

PHORMIUM, *New Zealand FLAX-PLANT.* See
FLAX-Plant, (*Append.*)

PHOSPHORUS. P. 6168, col. i. line 35, for quicksilver read quicklime.

PARENETIC, a term used to denote those who, without being absolutely mad, are subject to such strong fallies of imagination as in some measure pervert their judgment, and cause them act in a way different from the more rational part of mankind.

PILEUS, in Roman antiquity, was the ordinary cap or hat worn at public shows and sacrifices, and by the freedmen. It was one of the common rewards assigned to such gladiators as were slaves, in token of their obtaining freedom.

PINANG, the Chinese name of the areca catechu, *Lin.* See ARECA, (*Encycl.*)

PINGUICULA VULGARIS, *Butterwort*, or *York-*

shire Janicle. The Laplanders receive the milk of the rein-deer upon the fresh leaves of this plant, which they immediately strain off and set aside till it becomes somewhat acescent; and the whole acquires in a day or two the consistence of cream without separating the serum, and thus becomes an agreeable food. When thus prepared, a small quantity of the same has the property of rennet in producing the like change on fresh milk.

PIUS II. (Pope), before called *Aeneas Sylvius Bar-*
Piccolomini, was born at Corsignano of Siena in 1405.
He was, at the age of 26, secretary to Dominico Capra-
nico at the council of Bale, and had the provostship
of St Laurence's church in Milan. Afterwards Fre-
deric III. honoured him with the poetical crown, and
employed him in divers embassies to Rome, Man-
naples, Bohemia, &c. He managed several suc-
cessful negotiations, especially in the diet with the
Turks, which he called for the forming of a league against
at Ratibon and Francfort, where he delighted him-
self with wonderful eloquence. Calixt. III. made
him cardinal in 1456; and that pope died, he was
advanced to his place, and took the name of *Pius II.*
In 1458 he summoned the Christian princes against
the Turks; and would have led some troops himself, but
died at Ancona, whither he was going in order to
embark, in 1464, having sat six years, &c. His
works were published at Bale in 1571. He was a
person of true courage, singular prudence, the best
and most learned pope that reigned since the
ages before.

PLANTS, FOSSIL. Most species of tender and herbaceous plants are found at this day, in great abundance, buried at considerable depths in the earth, and converted, as it were, to the nature of the matter they lie among; fossil food is often found very little altered, and often imbricated with substances of al-

most all the different fossil kinds, and lodged in all the several strata, sometimes firmly imbedded in hard matter; sometimes loose: but this is by no means the case with the tenderer and more delicate subjects of the vegetable world. These are usually immersed either in a blackish slaty substance, found lying over the strata of coal, else in loose nodules of ferruginous matter of a pebblike form, and they are always altered into the nature of the substance they lie among: what we meet with of these are principally of the fern kind; and what is very singular, though a very certain truth, is, that these are principally the terms of American growth, not those of our own climate. The most frequent fossil plants are the polypody, spleen-wort, osmund, trichomanes, and the several larger and smaller ferns; but beside these there are also found pieces of the equisetum or horsetail, and joints of the articulated plants, as the clivers, maader, and the lile; and these have been too often mistaken for flowers; sometimes there are also found complete grasses, or parts of them, as also reeds, and other watery plants; sometimes the ears of corn, and not unfrequently the twigs or bark, and impressions of the bark, and fruit of the pine or fir kind, which have been, from their scaly appearance, mistaken for the skins of fishes; and sometimes, but that very rarely, we meet with mosses and sea-plants.

Many of the ferns not unfrequently found, are of very singular forms, and some species yet unknown to us; and the leaves of some appear set at regular distances, with round protuberances and cavities. The stipes which contain these plants split readily, and are often found to contain, on one side, the impression of the plant; and on the other the prominent plant itself: and, beside all that have been mentioned, there have been frequently supposed to have been found with us, ears of common wheat, and of the maize or Indian corn; the first being in reality no other than the commonest branches of the fern, and the other the thicker boughs of various species of that and of the pine kind, with their leaves fallen off; such branches in such a state cannot but afford many irregular tubercles and papillæ, and, in some species, such as are more regularly disposed.

These are the kinds most obvious in England; and these are either immersed in the slaty stone which constitutes whole strata, or in flatted nodules, usually of about three inches broad, which readily split into two pieces on being struck.

They are most common in Kent, on coal-pits near Newcastle, and the forest of Dean in Gloucestershire; but are more or less found about almost all the coal-pits, and many of our iron mines. Though these seem the only species of plants found with us, yet in Germany there are many others, and those found in different substances. A whitish stone, a little harder than chalk, frequently contains them: they are found also often in a grey stately stone of a firmer texture, not unfrequently in a blackish one, and at times in many others. Nor are the bodies themselves less various here than the matter in which they are contained: the leaves of trees are found in great abundance, among which those of the willow, poplar, whitethorn, and pear trees, are the most common; small branches of box, leaves of the olive-tree, and stalks of garden thyme, are also found there; and sometimes ears of the various species

cies of corn, and the larger as well as the smaller mofes in great abundance.

These feem the tender vegetables, or herbaceous plants, certainly found thus immerfed in hard ftone, and buried at great depths in the earth: others of many kinds there are alfo named by authors; but, as in bodies fo imperfect, errors are eafily fallen into, thefe feem all that can be afcertained beyond mere conjecture.

PLANTS, Method of PRESERVING them in their original Shape and Colour. Wash a fufficient quantity of fine fand, fo as perfectly to feparate it from all other fubftances; dry it; pafs it through a fieve to clear it from any grofs particles which would not rife in the washing: take an earthen vefel of a proper fize and form, for every plant and flower which you intend to preferve; gather your plants and flowers when they are in a ftate of perfection, and in dry weather, and always with a convenient portion of the ftalk: heat a little of the dry fand prepared as above, and lay it in the bottom of the vefel, fo as equally to cover it; lay the plant or flower upon it, fo as that no part of it may touch the fides of the vefel: lift or shake in more of the fame fand by little upon it, fo that the leaves may be extended by degrees, and without injury, till the plant or flower is covered about two inches thick: put the vefel into a ftove, or hot-houfe, heated by little and little to the 50th degree; let it ftand there a day or two, or perhaps more, according to the thicknefs and fucculence of the flower or plant; then gently shake the fand out upon a fheet of paper, and take out the plant, which you will find in all its beauty, the ftape as elegant, and the colour as vivid as when it grew.

Some flowers require certain little operations to preferve the adherence of their petals, particularly the tulip; with refpect to which it is neceffary, before it is buried in the fand, to cut the triangular fruit which riles in the middle of the flower; for the petals will then remain more firmly attached to the ftalk.

A hortus ficcus prepared in this manner would be one of the moft beautiful and ufeul curiofities that can be.

PLAY, in poetry, &c. See **DRAMA, TRAGEDY, COMEDY, &c.** (*Encycl.*)

PLAY-HOUSE. The moft ancient Englifh play-houfes were the Curtain in Shoreditch, and the Theatre. In the time of Shakefpeare, who commenced a dramatic writer about the year 1592, there were no lefs than ten theatres open, four private houfes, and fix that were called public theatres. Moft, if not all, of Shakefpeare's plays were performed either at the Globe, which was an hexagonal building, partly open to the weather and partly covered with reeds, on the fouthern fide of the river Thames, called the *Bank-fide*, and a public theatre, where they always acted by day-light; or at the theatre in Blackfriars, which was a private play-houfe, and where plays were ufually reprefented by candle-light. Both thefe belonged to the fame company of comedians, viz. his majefty's fervants; which title they affumed after a licence had been granted to them by king James in 1603, having before this time been called the fervants of the lord chamberlain. The exhibitions at the Globe feem to have been calculated chiefly for the lower clafs of peo-

ple, and thofe at Blackfriars for a more felect and judicious audience. The former was a fummer, and the latter a winter theatre. Many of our ancient dramatic pieces were performed in the yards of carrier's inns; in which, in the beginning of queen Elizabeth's reign, the comedians, who then firft united themfelves in companies, erected an occasional ftage. The form of thefe temporary play-houfes feems to be preferved in our modern theatre. Many circumftances concur to render it probable, that our ancient theatres, in general, were only furnifhed with curtains, which opened in the middle, and a fingle fcene compofed of tapeftry, fometimes ornamented with pictures. In the year 1605, Inigo Jones exhibited an entertainment at Oxford, in which moveable fcenes were ufed; but they were not then ufed in the public theatres. When Sir William Davenant firft opened, by virtue of his patent, the duke of York's theatre in Lincoln's-Inn fields, in the fpring of the year 1662, with one of his own plays, the ftege of Rhodes, then fcenes made their firft appearance upon the Englifh ftage; and about the fame time actresses were alfo introduced, probably by him, in imitation of the foreign theatres; and Mrs Betterton is faid to have been the firft woman that appeared on the Englifh ftage. Before this time female characters were reprefented by boys or young men. In the time of Shakefpeare plays began at one o'clock in the afternoon, and the exhibition was ufually finifhed in two hours; and fo late as 1667, they commenced at three o'clock. See *Malone's Supplemental Observations to Steevens's edition of Shakefpeare*.

If any perfons fhall, in plays, &c. jellingly or profanely ufe the name of God, they fhall forfeit 10 l. Stat. 1. Jac. I. cap. 21. And players fpeaking any thing in derogation of religion, &c. are liable to forfeitures and imprifonments. 1. Eliz. Alfo acting plays or interludes on a Sunday is fubject to penalties, by 1 Car. I. cap. 1. No perfon fhall act any new play, or addition to an old one, &c. unlefs a true copy thereof, figned by the mafter of the play-houfe, be fent to the lord chamberlain 14 days before it be acted, who may prohibit the reprefenting any ftage-play; and perfons acting contrary to fuch prohibitions fhall forfeit 50 l. and their licences, &c. Stat. 10. Geo. II. cap. 28. And by this ftatute, no licence is to be given to act plays, but in the city and liberties of Weftminfter, or places of his majefty's refidence.

PLEASURE. (*Encycl.*) Pleafure and pain are no other than engines in nature's hand, whereby we are directed to confult our own prefervation, and avoid our ruin. To things that may contribute to the one, as food, venery, &c. fhe has annexed pleafure; and to thofe that may conduce to the other, as hunger, difeafes, &c. pain. She durft not leave it to our difcretion, whether we would preferve and propagate the fpecies or not; but, as it were, conftains us to both. Were there no pleafure in eating, nor pain in hunger, what numbers would be ftarved through negligence, forgetfulnefs, or fluth? What is it induc-es people to the office of generation, but pleafure? Without this the world had fcarce fubfifted to this time.

Among the multiplicity of things to be done, and to be avoided, for the prefervation of animal life, &c. how fhould we have diftinguifhed between the one and the

Pleasure
Point.

Polygal,
Polygamy.

the other, but for the sensation of pleasure and pain? These are not only spurs to urge us on, but also guides to direct us whither we are to go. Wherever nature has fixed a pleasure, we may take it for granted she there enjoins a duty; and something is to be there done, either for the individual, or for the species.

Hence it is, that our pleasures vary at different stages of life; the pleasures, *e. g.* of a child, a youth, a grown man, an old man, &c. all tending to those particular things required by nature in that particular state of life, either for the preservation simply, or jointly for that and propagation, &c.

Hence, from the different constitutions of the body, at different ages, it were very easy to account for all the particular tastes and pleasures thereof: not by deducing the pleasures mechanically from the disposition of the organs in that state, but by considering what is necessary for the perfection and well-being of the individual in that state, and what is to contribute to that of the species. In a child, *e. g.* mere preservation in the present state is not enough; it must likewise grow: to bring this to pass, nature has made the returns of hunger, &c. more frequent, as well as more acute, and the pleasures of feeding more exquisite. And that the excess of aliment, in proportion to the bulk of the body, may be dispensed with, she has made one of the great pleasures of this state to consist in a series of sportive exercises; by means whereof the parts of the body come to be opened and expanded, and arrive at maturity. This done, the pleasures that conducted thereto disappear; and others, suited to the new state, succeed.

PLUMBAGO, LEAD-WORT; a genus of the monogynia order, belonging to the pentandria class of plants. There are four species; the most remarkable of which are the *Europæa* and *Zeylonica*. The first grows naturally in the southern parts of Europe, and has a perennial root striking deep in the ground. There are many slender channelled stalks, about three feet high, terminated by tufts of small funnel-shaped flowers, of a blue or white colour. The second grows naturally in both the Indies. The upper part of the stalk and empalement are covered with a glutinous juice, which catches the small flies that light upon it. The former species is propagated by parting the roots, and by seeds; but the latter is too tender to thrive in the open air in this country.

POE-BIRD, in ornithology, is an inhabitant of some of the South Sea islands, where it is held in great esteem and veneration by the natives. It goes by the name of *Kogo* in New Zealand; but is better known by that of *Pœ-bird*. It is somewhat less than our blackbird. The feathers are of a fine mazarine blue, except those of its neck, which are of a most beautiful silver grey, and two or three short white ones which are on the pinion-joint of the wing. Under its throat hang two little tufts of curled snow-white feathers, called its *poies*, (the Otaheitian word for ear-rings); which occasioned the name of *pœ bird* being given to it. It is remarkable for the sweetness of its note, as well as the beauty of its plumage. Its flesh is also delicate food. See Plate CCLXIV.

POINT-BLANK, in gunnery, denotes the shot of a gun levelled horizontally, without either mounting or sinking the muzzle of the piece.—In shooting point-

blank, the shot or bullet is supposed to go directly forward, in a straight line, to the mark; and not to move in a curve, as bombs and highly elevated random-shots do.—When a piece stands upon a level plane, and is laid level, the distance between the piece and the point where the shot touches the ground first, is called the *point-blank* range of that piece; but as the same piece ranges more or less, according to a greater or less charge, the point-blank range is taken from that of a piece loaded with such a charge as is used commonly in action. It is, therefore, necessary that these ranges of all pieces should be known, since the gunner judges from thence what elevation he is to give to his pieces when he is either farther from or nearer to the object to be fired at; and this he can do pretty nearly by sight, after considerable practice.

POLYGALA. At the end of the paragraph, delete the remark which follows the word *rattlesnake*.

POLYGAMY, (*Encycl.*) Dr Percival, Phil. Trans. vol. lvi. part i. p. 163. has very justly observed, that the practice is brutal, destructive to friendship and moral sentiment, inconsistent with one great end of marriage the education of children, and subversive of the natural rights of more than half of the species. Besides, it is injurious to population, and therefore can never be countenanced or allowed in a well-regulated state: for, though the number of females in the world may considerably exceed the number of males, yet there are more men capable of propagating their species than women capable of bearing children; and it is a well-known fact, that Armenia, in which a plurality of wives is not allowed, abounds more with inhabitants than any other province of the Turkish empire.

Yet Selden has proved, in his *Uxor Hebraica*, that plurality of wives was allowed of, not only among the Hebrews, but also among all other nations, and in all ages. It is true, the ancient Romans were more severe in their morals, and never practised it, though it was not forbid among them: and Mark Anthony is mentioned as the first who took the liberty of having two wives.

From that time it became pretty frequent in the empire, till the reigns of Theodosius, Honorius, and Arcadius, who first prohibited it by express law in 393. After this the emperor Valentinian, by an edict, permitted all the subjects of the empire, if they pleased, to marry several wives: nor does it appear, from the ecclesiastical history of those times, that the bishops made any opposition to this introduction of polygamy. In effect, there are some even among the Christian casuists, who do not look on polygamy as in itself criminal. Jurieu observes, that the prohibition of polygamy is a positive law; but from which a man may be exempted by sovereign necessity. Baillet adds, that the example of the patriarchs is a very powerful argument in favour of polygamy.

It has been much disputed among the doctors of the civil law, whether polygamy be adultery. In the Roman law it is called *stuprum*, and punished as such, that is, in some cases, capitally. But a smaller punishment is more consistent with the Jewish law, wherein the prohibition of adultery is perpetual, but that of polygamy temporary only.

In Germany, Holland, and Spain, this offence is
1 diff.

poly. differently punished. By a constitution of Charles V. it was a capital crime. By the laws of ancient and modern Sweden, it is punished with death. In Scotland it is punished as perjury.

In England it is enacted by statute 1 Jac. I. cap. 11. that if any person, being married, do afterwards marry again, the former husband or wife being alive, it is felony, but within the benefit of clergy. The first wife in this case shall not be admitted as an evidence against her husband, because she is the true wife; but the second may, for she is indeed no wife at all; and so *vice versa*, of a second husband. This act makes an exception to five cases, in which such second marriage, tho' in the three first it is void; is, however, no felony. 1. Where either party hath been continually abroad for seven years, whether the party in England had notice of the other's being living or no. 2. Where either of the parties hath been absent from the other seven years, within this kingdom, and the remaining party hath had no notice of the other's being alive within that time. 3. Where there is a divorce or separation *a mensa et thoro* by sentence in the ecclesiastical court. 4. Where the first marriage is declared absolutely void by any such sentence, and the parties loosed *a vinculo*. Or, 5. Where either of the parties was under the age of consent at the time of the first marriage; for in such case the first marriage was voidable by the disagreement of either party, which this second marriage very clearly amounts to. But if at the age of consent the parties had agreed to the marriage, which completes the contract, and is indeed the real marriage, and afterwards one of them should marry again, judge Blackstone apprehends that such second marriage would be within the reason and penalties of the act.

Bernardus Ochinus, general of the order of Capuchins, and afterwards a Protestant, published, about the middle of the 16th century, Dialogues in favour of Polygamy, which were answered by Theodore Beza. And about the conclusion of the last century we had at London an artful treatise published in behalf of a plurality of wives, under the title of *Polygamia Triumphatrix*: the author whereof assumes the name of *Theophilus Aletheus*; but his true name was *Lysurus*: he was a native of Saxony. It has been answered by several.

In the year 1780, the rev. Mr Madan published a treatise, artfully vindicating and strongly recommending polygamy, under the title of *Thelyphthora*; or, *A Treatise on Female Ruin, in its Causes, Effects, Consequences, Prevention, and Remedy*, &c. Marriage, according to this writer, simply and wholly consists in the act of personal union, or *actus coitus*. Adultery, he says, is never used in the sacred writings but to denote the defilement of a betrothed or married woman, and to this sense he restricts the use of the term; so that a married man, in his opinion, is no adulterer, if his commerce with the sex be confined to single women, who are under no obligations by espousals or marriage to other men: but, on the other hand, the woman who should dare to have even but once an intrigue with any other man besides her husband, (let him have as many wives as Solomon), would, *ipso facto*, be an adulteress, and ought, together with her gallant, to be punished with immediate death. This,

he boldly says, is the law of God: and on this foundation he limits the privilege of polygamy to the man; in support of which he refers to the polygamous connections of the patriarchs and saints of the Old Testament, and infers the lawfulness of their practice from the blessings which attended it, and the laws which were instituted to regulate and superintend it. He contends for the lawfulness of Christians having, like the ancient Jews, more wives than one; and labours much to reconcile the genius of the evangelical dispensation to an arrangement of this sort. With this view he asserts, that there is not one text in the New Testament that even hints at the criminality of a polygamous connection; and he would infer from St Paul's direction that bishops and deacons should have but one wife, that it was lawful for laymen to have more. Christ, he says, was not the giver of a new law; but the business of marriage, polygamy, &c. had been settled before his appearance in the world, by an authority which could not be revoked. Besides, this writer not only thinks polygamy lawful in a religious, but advantageous in a civil light, and highly politic in a domestic view.

In defence of his notion of marriage, which, according to his account of it, consists in the union of man and woman as one body, the effects of which in the sight of God no outward forms or ceremonies of man's invention can add to or detract from, he grounds his principal argument on the Hebrew words made use of in Gen. ii. 24. to express the primitive institution of marriage, viz. *והיו בשר אחד*, rendered by the LXX. *πρωτοκληνησιναι προς την υνικαιαν αυην*, which translation is adopted by the evangelist (Mat. xix. 5.) with the omission only of the superfluous proposition (*προς*) after the verb. Our translation, "shall cleave to his wife," doth not, he says, convey the idea of the Hebrew, which is literally, as Montanus renders the words, "shall be joined or cemented *in* his woman, and they shall become (*i. e.* by this union) one flesh." But on this criticism it is well remarked, that both the Hebrew and Greek terms mean simply and literally attachment or adherence; and are evidently made use of in the sacred writings to express the whole scope of conjugal fidelity and duty, though he would restrain them to the groffer part of it.

With respect to the Mosaic law, for which Mr Madan is a warm advocate, it was certainly a local and temporary institution, adapted to the ends for which it was appointed, and admirably calculated, in its relation to marriage, to maintain and perpetuate the separation of the Jewish people from the Gentiles. In attempting to depreciate the outward forms of marriage, this writer would make his readers believe, that because none are explicitly described, therefore none existed; and consequently that they are the superfluous ordinances of human policy. But it is evident, from comparing Ruth iv. 10, 13. with Tobit. vii. 13, 14. and from the case of Dinah, related Gen. xxxiv. that some forms were deemed essential to an honourable alliance by the patriarchs and saints under the Old Testament, exclusive of the carnal knowledge of each other's persons. It is also evident in the case of the woman of Samaria, whose connection with a man not her husband, is mentioned in John iv. that something besides cohabitation is necessary

Polygamy. fary to constitute marriage in the sight of God.

Having stated his notion of marriage, he urges, in defence of polygamy, that, notwithstanding the seventh commandment, it was allowed by God himself, who made laws for the regulation of it, wrought miracles in support of it by making the barren woman fruitful, and declared the issue legitimate to all intents and purposes. God's allowance of polygamy is argued from Exod. xxi. 10. and particularly from Deut. xxi. 15. which, he says, amounts to a demonstration. This passage, however, at the utmost, only presupposes that the practice might have existence among so hard-hearted and sordid a people as the Jews; and therefore wisely provides against some of its more unjust and pernicious consequences, such as tended to affect the rights and privileges of heirship. Laws enacted to regulate it cannot be fairly urged in proof of its lawfulness on the author's own hypothesis; because laws were also made to regulate divorce, which Mr Madan condemns as absolutely unlawful, except in cases of adultery. Besides, it is more probable that the "hated wife" had been dismissed by a bill of divorcement, than that she was retained by her husband; and moreover, it is not certain that the two wives, so far from living with the same husband at the same time, might not be dead; for the words may be rendered thus, "if there *should have been* to a man two wives, &c." The words expressing the original institution of marriage, Gen. ii. 24. compared with Mat. xix. 4, 5, 8. afford insuperable objections against Mr Midan's doctrine of polygamy.

If we appeal on this subject, from the authority of scripture to the writings of the earliest fathers in the Christian church, there is not to be found the faintest trace of any thing resembling a testimony to the lawfulness of polygamy; on the contrary, many passages occur, in which the practice of it is strongly and explicitly condemned.

We shall close this article with the words of an excellent anonymous writer, to whose critique on Mr Madan's work we are indebted for the above remarks: "In a word, when we reflect, that the primitive institution of marriage limited it to one man and one woman; that this institution was adhered to by Noah and his sons, amidst the degeneracy of the age in which they lived, and in spite of the examples of polygamy which the accursed race of Cain had introduced; when we consider how very few (comparatively speaking) the examples of this practice were among the faithful; how much it brought its own punishment with it; and how dubious and equivocal those passages are in which it appears to have the sanction of divine approbation; when to these reflections we add another, respecting the limited views and temporary nature of the more ancient dispensations and institutions of religion—how often the imperfections and even vices of the patriarchs and people of God, in old time, are recorded, without any express notification of their criminality—how much is said to be commanded, which our reverence for the holiness of God and his law, will only suffer us to suppose, were, for wise ends, permitted—how frequently the messengers of God adapted themselves to the genius of the people to whom they were sent, and the circumstances of the times in which they lived;—above all, when we consider the purity, equity, and

benevolence of the Christian law; the explicit declarations of our Lord, and his apostle St Paul, respecting the institution of marriage, its design and limitation;—when we reflect too, on the testimony of the most ancient fathers, who could not possibly be ignorant of the general and common practice of the apostolic church; and, finally, when to these considerations we add those which are founded on justice to the female sex, and all the regulations of domestic economy and national policy, we must wholly condemn the revival of polygamy; and thus bear our honest testimony against the leading design of this dangerous and ill-advised publication."

POLYPE, or POLYPUS, in zoology, a small fresh-water insect, belonging to the genus of hydra, in the class of worms, and order of zoophytes, in the Linnean system; which, when cut into a number of separate pieces, becomes in a day or two so many distinct and separate animals; each piece having the surprising property of producing a head and tail, and the other organs necessary for life, and all the animal-functions.

The first discovery of this animal was owing to M. Leuwenhoek, who, in the year 1703, presented to the Royal Society of London a description of it, and an account of its uncommon way of producing its young; but the discovery of its amazing property of reproducing the several organs from its various pieces was not made till the year 1740, by M. Trembley, at the Hague.

The production of its young is indeed different from the common course of nature in other animals: for the young one issues from the sides of its parent in form of a small pimple or protuberance, which, lengthening and enlarging every hour, becomes in about two days a perfect animal, and drops from off its parent to exist for itself: but before it does this, it has often another growing from its side; and sometimes a third from it, even before the first is separated from its parent.

M. Trembley observes, that there is no distinguishable place in the body of the polypus by which the young are brought forth. He has seen some of them that have produced young ones from all the exterior parts of their bodies.

They breed quicker in hot than in cold weather; and what is very extraordinary is, that there never has yet been discovered among them any distinction of sex or appearance of copulation; every individual of the whole species being prolific, and that as much if kept separate, as if suffered to live among others.

If the method of this little animal's producing its young be very amazing, its reproduction of the several parts, when cut-off, is much more so. The discovery of this was perfectly accidental; for M. Trembley, who had often met with the creature in the water, and from its fixed residence in one place, and some other observations, not being able to determine whether it was an animal or a vegetable, made the trial by cutting it asunder; when, to his amazement, he found, that in a few days each of those pieces was become a perfect animal, the head part having shot forth a tail, and the tail a head.

A thousand other trials, by cutting the animal in different manners, first by M. Trembley, and afterwards, at his request, by Mons. Reaumur and Bernard

Polygamy.
Polype.

de Jussieu at Paris, and Mr Folkes, Mr Baker, and the other naturalists in England, were the result of this; and all succeeded in the same manner by those who repeated them.

It is not easy to say what is the size of this creature; for it can contract or extend its body at pleasure from the length of an inch or more, and the thickness of a hog's bristle, to the shortness of a single line, with a proportionable increase of thickness. Its body is round and tubular; at one end of which is the head, surrounded with six, eight, ten, or more arms, with which it catches its prey; and at the other, the anus and tail, by which it fixes itself to any thing it pleases.

There have been many different species of it discovered; the most elegant of which, the *polype a panache*, or plumed polype of M. Trembley, seems much to resemble the wheel-animal † (so called from having the appearance of two wheels in its head) which Mr Leuwenhoek discovered, living in a sheath or case, and affixed to the roots of duckweed.

All the species are found in clear and slowly-running waters, adhering by the tail to sticks, stones, and water plants; and live on small insects. They are easily kept alive a long time in glasses, often changing the water, keeping the glasses clean, and feeding them with a small red worm common in the mud of the Thames, or with other small insects.

The creature has its name from the Greek πολυς "many," and πύ; a "foot," signifying an animal with many feet; but a more apposite one might easily have been invented, since it has in reality no feet at all. What were originally taken for feet, are what have since been called its horns, and of late, more properly, its arms, their office being to catch its prey.

This animal is first of a worm-shaped figure, and of the same kind of tender substance with the horns of a common snail: it adheres by one end, like a sucker, to water-plants and other substances; the other end, which is the head, is surrounded by many arms or feeders, placed like rays round a centre: this centre is its mouth; and with these tender arms, which are capable of great extension, it seizes minute worms, and various kinds of water-insects, and brings them to its mouth; and often swallows bodies larger than itself, having a surprising property of extending its mouth wider in proportion than any other animal. After its food is digested in its stomach, it returns the remains of the animals upon which it feeds through its mouth again, having no other observable excretory. In a few days there appear small knobs or papillæ on its sides: as these increase in length, little fibres are seen rising out of the circumference of their heads, as in the parent animal; which fibres they soon begin to use for the purpose of procuring nourishment, &c. When these are arrived at mature size, they send out other young ones on their sides in the same manner; so that the animal branches out into a numerous offspring, united together, and growing out of one common parent. Each of these provides nourishment not only for itself, but for the whole society; an increase of the bulk of one polype, by its feeding, tending to an increase in the rest. Thus a polype of the fresh-water kind becomes like a plant branched out, or composed of many bodies; each of which has this singular cha-

racteristic, that if one of them be cut in two in the middle, the separated part becomes a complete animal, and soon adhering to some fixed base, like the parent from which it was separated, produces a circle of arms: a mouth is formed in the centre; it increases in bulk, emits a numerous progeny, and is in every respect as perfect an animal as that from which it was severed.

The several strange properties recorded of this animal, though very surprising, are, however, none of them peculiar to it alone. The Surinam toad is well known to produce its young, not in the ordinary way, but in cells upon its back. Mr Sherwood has very lately discovered the small eels in four parts to be without exception full of living young ones. And as to the most amazing of all its properties, the reproduction of its parts, we know the crab and lobster, if a leg be broken off, always produce a new one: and M. Bonet, M. Lyonet, Monf. de Reaumur, and Mr Folkes, have all found, on experiment, that several earth and water worms have the same property, some of them even when cut into thirty pieces. The urtica marina, or sea-nettle, has been also found to have the same; and the sea star-fish, of which the polype is truly a species, though it had long escaped the searches of the naturalists, was always well known by the fishermen to have it also.

POLYPE, marine, is different in form from the fresh-water polype already described; but is nourished, increases, and may be propagated after the same manner; Mr Ellis having often found, in his inquiries, that small pieces cut off from the living parent, in order to view the several parts more accurately, soon gave indications that they contained not only the principles of life, but likewise the faculty of increasing and multiplying into a numerous issue. It has been lately discovered and sufficiently proved by Peyssonel, Ellis, Jussieu, Reaumur, Donati, &c. that many of those substances, which had formerly been considered by naturalists as marine vegetables or sea-plants, are in reality animal-productions; and that they are formed by polypes of different shapes and sizes, for their habitation, defence, and propagation. To this class may be referred the corals, corallines, keratophyta, eschara, sponges, and alcyonium: nor is it improbable that the more compact bodies, known by the common appellations of *star-fishes*, *brain-fishes*, *petrified fungi*, and the like, brought from various parts of the East and West Indies, are of the same origin. To this purpose Mr Ellis observes, that the ocean, in all the warmer latitudes near the shore, and wherever it is possible to observe, abounds so much with animal-life, that no inanimate body can long remain unoccupied by some species. In those regions, the ships bottoms are soon covered with the habitations of thousands of animals: rocks, stones, and every thing lifeless, are covered with them instantly; and even the branches of living vegetables that hang into the water, are immediately loaded with the spawn of different animals, shell-fish of various kinds: and shell-fish themselves, when they become impotent and old, are the basis of new colonies of animals, from whose attacks they can no longer defend themselves. For a farther account of this system, see CORAL and CORALLINES.

POLYTRICHUM, (*Encycl.*) See Plate CCCXXI.

POPERY, in Ecclesiastical History, comprehends the religious doctrines and practices adopted and maintained by the church of Rome. The following summary, extracted chiefly from the decrees of the council of Trent, continued under Paul III. Julius III. and Pius IV. from the year 1545 to 1563, by successive sessions, and the creed of pope Pius IV. subjoined to it, and bearing date November 1564, may not be unacceptable to the reader. One of the fundamental tenets, strenuously maintained by popish writers, is the infallibility of the church of Rome; though they are not agreed, whether this privilege belongs to the pope, or a general council, or to both united; but they pretend that an infallible living judge is absolutely necessary to determine controversies, and to secure peace in the Christian church. However, Protestants allege, that the claim of infallibility in any church is not justified by the authority of Scripture; much less does it pertain to the church of Rome; and that it is inconsistent with the nature of religion, and the personal obligations of its professors; and that it has proved ineffectual to the end for which it is supposed to be granted, since popes and councils have disagreed in matters of importance, and they have been incapable, with the advantage of this pretended infallibility, of maintaining union and peace.

Another essential article of the popish creed is the supremacy of the pope, or his sovereign power over the universal church. On this subject it is maintained, that every Christian, under pain of damnation, is bound to be subject to the pope; that no appeals may be made from him; and that he alone is the supreme judge of all persons, in all ecclesiastical causes, but that he himself can be judged by no man. To this purpose they assert, that the church of Rome is the catholic church; the mother and mistress of all churches; that the pope is the vicar of Christ, successor of St Peter, and the supreme pastor over all the world. And they likewise assert his dominion over temporal princes; pretending that he may over-rule what they command; excommunicate and depose them, if they contradict his commands; and absolve their subjects from allegiance, and exempt the clergy from their jurisdiction.

This exorbitant power hath been challenged by the pope for many successive ages, and in several instances actually exercised. Thus Gregory VII. excommunicated the emperor Henry IV. and gave away his kingdoms to Rudolphus duke of Sweden. Gregory IX. excommunicated the emperor Frederick II. and absolved his subjects from their oath of allegiance. Pope Paul III. excommunicated and deposed Henry VIII. king of England, and commanded all his subjects, under a curse, to withdraw their obedience from him. Pope Pius V. and Gregory XIII. damned and deposed queen Elizabeth, and absolved her subjects from their allegiance. And this practice has been warranted by the decrees of the third Lateran council under pope Alexander III. and by the fourth Lateran council under pope Innocent III. though it is contrary to the express language of Scripture, to the doctrine and conduct of the apostles and primitive fathers, and to the confessions and practice of the ancient bishops of Rome, and altogether inconsistent with the rights of government and the welfare of society.

Farther, the doctrine of the seven sacraments is a peculiar and distinguishing doctrine of the church of Rome: these are baptism, confirmation, the eucharist, penance, extreme unction, orders, and matrimony.

The council of Trent (sess. 7. can. 1.) pronounces an anathema on those who say, that the sacraments are more or fewer than seven, or that any one of the above number is not truly and properly a sacrament. And yet it does not appear that they amounted to this number before the 12th century, when Hugo de St Victor and Peter Lombard, about the year 1144, taught that there were seven sacraments. The council of Florence, held in 1438, was the first council that determined this number. These sacraments confer grace, according to the decree of the council of Trent (sess. 7. can. 8.) *ex opere operato*, by the mere administration of them: three of them, viz. baptism, confirmation, and orders, are said (can. 9.) to impress an indelible character, so that they cannot be repeated without sacrilege; and the efficacy of every sacrament depends on the intention of the priest by whom it is administered (can. 11.) Pope Pius expressly enjoins, that all these sacraments should be administered according to the received and approved rites of the catholic church. With regard to the eucharist in particular, we may here observe, that the church of Rome holds the doctrine of transubstantiation; the necessity of paying divine worship to the consecrated bread, or host; the propitiatory sacrifice of the mass, according to their ideas of which Christ is truly and properly put to death as a sacrifice as often as the priest says mass; and solitary mass, in which the priest alone, who consecrates, communicates, and allows communion only in one kind, viz. the bread, to the laity. Sess. 14.

The doctrine of merits is another distinguishing tenet of popery; with regard to which the council of Trent has expressly decreed (sess. 6. can. 32.) that the good works of justified persons are truly meritorious; deserving not only an increase of grace, but eternal life, and an increase of glory; and it has anathematized all who deny this doctrine. Of the same kind is the doctrine of satisfactions; which supposes that penitents may truly satisfy, by the afflictions they endure under the dispensations of Providence, or by voluntary penances to which they submit, for the temporal penalties of sin, to which they are subject, even after the remission of their eternal punishment. Sess. 6. can. 30. and sess. 14. can. 8. and 9. In this connection we may mention the popish distinction of venial and mortal sins: the greatest evils arising from the former are the temporary pains of purgatory; but no man, it is said, can obtain the pardon of the latter without confession to a priest, and performing the penances which he imposes.

The council of Trent (sess. 14. can. 1.) has expressly decreed, that every one is accused, who shall affirm that penance is not truly and properly a sacrament instituted by Christ in the universal church, for reconciling those Christians to the divine majesty, who have fallen into sin after baptism: and this sacrament, it is declared, consists of two parts, the matter and the form; the matter is the act of the penitent, including contrition, confession, and satisfaction; the form of it is the act of absolution on the part of the priest. Accordingly it is enjoined, that it is the duty of every man,

Popery.

man, who hath fallen after baptism, to confess his sins once a year, at least, to a priest: that this confession is to be secret; for public confession is neither commanded nor expedient: and that it must be exact and particular, including every kind and act of sin, with all the circumstances attending it. When the penitent has so done, the priest pronounces an absolution; which is not conditional or declarative only, but absolute and judicial. This secret, or auricular confession, was first decreed and established in the fourth council of Lateran, under Innocent III. in 1215, (cap. 21.) And the decree of this council was afterwards confirmed and enlarged in the council of Florence, and in that of Trent, which ordains, that confession was instituted by Christ, that by the law of God it is necessary to salvation, and that it has been always practised in the Christian church. As for the penances imposed on the penitent by way of satisfaction, they have been commonly the repetition of certain forms of devotion, as pater-nosters, or ave-marias, the payment of stipulated sums, pilgrimages, fasts, or various species of corporal discipline. But the most formidable penance in the estimation of many, who have belonged to the Romish communion, has been the temporary pains of purgatory. But under all the penalties which are inflicted or threatened in the Romish church, it has provided relief by its indulgences, and by its prayers or masses for the dead, performed professedly for relieving and releasing the souls that are detained in purgatory.

Another article that has been long authoritatively enjoined and observed in the church of Rome, is the celibacy of her clergy. This was first enjoined at Rome by Gregory VII. about the year 1074, and established in England by Anselm archbishop of Canterbury about the year 1175; though his predecessor Lanfranc had imposed it upon the prebendaries and clergy that lived in towns. And though the council of Trent was repeatedly petitioned by several princes and states to abolish this restraint, the obligation of celibacy was rather established than relaxed by this council; for they decreed, that marriage contracted after a vow of continence is neither lawful nor valid; and thus deprived the church of the possibility of ever restoring marriage to the clergy. For if marriage, after a vow, be in itself unlawful, the greatest authority upon earth cannot dispense with it, nor permit marriage to the clergy, who have already vowed continence.

To the doctrines and practices above recited may be further added the worship of images; to justify which, the Papists often leave the second commandment out of their catechisms: the invocation of saints and angels, with respect to which the council of Trent decreed, that all bishops and pastors, who have the cure of souls, do diligently instruct their flocks, that it is good and profitable humbly to pray unto the saints, and to have recourse to their prayers, help, and aid; for which practice no scripture command or example, nor any testimony within the first 300 years after Christ, can be pleaded: the worship of sacred relics, by which they understand not only the bodies and parts of the bodies of the saints, but any of those things that appertained to them, and which they touched: and the celebration of divine service in an unknown tongue; to which purpose the council of

Trent hath denounced an anathema on any one who shall say that mass ought to be celebrated only in the vulgar tongue, sess. 25, and sess. 22, can. 9. Though the council of Lateran under Innocent III. in 1215 (can. 9.) had expressly decreed, that, because in many parts within the same city and diocese, there are many people of different manners and rites mixed together, but of one faith, the bishops of such cities or dioceses should provide fit men for celebrating divine offices, according to the diversity of tongues and rites, and for administering the sacraments.

We shall only add, that the church of Rome maintains, that unwritten traditions ought to be added to the holy Scriptures, in order to supply their defect, and regarded as of equal authority; that the books of the Apocrypha are canonical scripture; that the vulgar edition of the Bible is to be deemed as authentic; and that the Scriptures are to be received and interpreted according to that sense which the holy mother church, to whom it belongs to judge of the true sense, hath held, and doth hold, and according to the unanimous consent of the fathers.

Such are the principal and distinguishing doctrines of Popery, most of which have received the sanction of the council of Trent; and that of the creed of pope Pius IV. which is received, professed, and sworn to by every one who enters into holy orders in the church of Rome; and at the close of this creed, we are told, that the faith contained in it is so absolutely and indispensably necessary, that no man can be saved without it.

Many of the doctrines of Popery were relaxed, and very favourably interpreted by M. de Meaux, bishop of Condom, in his Exposition of the Doctrine of the Catholic Church, first printed in the year 1671: but this edition, which was charged with perverting, in endeavouring to palliate, the doctrine of the church, was censured by the doctors of the Sorbonne, and actually suppressed; nor does it appear that they ever testified their approbation in the usual form of subscription and altered editions.

PORELLA, in botany, the name of a genus of mosses, the characters of which are these: The capsules contain a powder like those of the other mosses; and they have neither operculum, calyptra, nor pedicel; and their manner of shedding their powder is not by separating into two parts, like those of the selago and lycopodium, but by opening into several holes on all sides.

Of this genus of mosses there is only one known species; this is called by Dillenius the *bluntly pinnated porella*, and grows in wet places in Virginia, Pennsylvania, Maryland, and other parts of North America.

PORPITES, the HAIR-BUTTON STONE, in Natural History, a name given by authors to a small species of fossil coral; which is usually of a rounded figure considerably flattened, and striated from the centre every way to the circumference. These are of different sizes, and of different colours, as greyish, whitish, brownish, or bluish, and are usually found immersed in stone. See Plate CCCXVII.

POTSDAM, or POSTDAM, a town of Germany in the circle of Upper Saxony, with a palace, belonging to the king of Prussia. It is seated in an island ten miles in circumference, formed by the rivers Sprae and Havel.

rian.

Havel. The palace is very curious, and finely built upon a delightful spot 10 miles west of Berlin. E. Long. 13. 42. N. Lat. 52. 34.

PREDESTINARIAN, a person who adheres to the doctrine of absolute predestination. See **PREDESTINATION**, (*Encycl.*)

St Augustin is looked on as the founder of the sect of Predestinarians, he being the first of the fathers that seems to have asserted the doctrine in such express terms; though the Janseists and Jesuits are still greatly divided about the real doctrine of St Augustin in this article, each interpreting him consistently with their own scheme.

Father Simond contends for an ancient sect of Predestinarians, or Predestinians, *Prædestiniani*, contemporary with St Augustin himself, and who had their rise in Africa, in the monastery of Adrumetum, from a misunderstanding of St Augustin's doctrine. Hence they were led into a notion, that God not only predestinated the wicked to eternal punishment, but also to the guilt and transgression for which they are punished; and that thus both the good and bad actions of all men were determined from eternity by a divine decree, and fixed by an inevitable necessity.

It is added, that the opinion spread thence throughout the Gauls; where one of them, a priest, named *Lucidus*, was condemned by Faustus bishop of Rheggio, and his sentence was confirmed by two councils.

However, the existence of this Predestinarian sect has been denied by many learned men, particularly the president Mauguin, and considered as an invention of the Semi-pelagians, designed to decry the followers of Augustin, by attributing to him unjustly this dangerous and pernicious error. Nor does it appear, though there might have been persons who embraced the Predestinarian opinions, that the abettors of them ever formed themselves into a sect.

The doctrine was again broached in the ninth century by Godeschalvus, a Benedictine; who, as Hincmar, in a letter to pope Nicolas, says, maintained with the ancient Predestinarians, who had been already anathematized, that God predestinated some to eternal life, and others to eternal death; that God did not will all people to be saved; that Jesus Christ did not die for all, but only the elect, or those that are saved, &c.

This doctrine was again condemned in a synod held at Mentz, A. D. 848, and by a council at Quiercy, A. D. 849; in consequence of which Godeschalvus was treated with the utmost barbarity, and compelled to burn with his own hands the justification of his opinion, which he had presented to the council at Mentz. He was then cast into prison, where he died in the year 868 or 869, maintaining with his last breath the doctrine for which he had suffered.

The decrees of the former council were confirmed in a new council which met at Quiercy, A. D. 853, but they were declared null by a council assembled at Valence, A. D. 855; and the decrees of this council were confirmed by the council of Langres in the year 859, and in 860 by the council of Touli.

This controversy was revived in the 16th century by Calvin, who maintained, that the everlasting condition of mankind in a future world was determined from all eternity; and that God, in predestinating from all eternity one part of mankind to everlasting happiness, and another to endless misery, was led to make this

Prede-
mination.

distinction by no other motive than his own good pleasure and free will. This opinion was, in a very short time, propagated through all the reformed churches, by the writings of Calvin, and by the ministry of his disciples; and in some places was inserted in the national creeds and confessions, and thus made a public article of faith.

The unhappy controversy, which took its rise from this doctrine, was opened at Straßburg, in the year 1560, by Jerome Zanchius, an Italian ecclesiastic, who was particularly attached to the sentiments of Calvin, and carried on in a manner that contributed very much to exasperate the passions and foment the discord of the contending parties.

The Predestinarian opinions have been maintained by considerable numbers, both in Popish and Protestant countries; and in our own country in particular, they have had many zealous advocates.

We shall here observe, that they have undergone a kind of relaxation by those who have been denominated *Baxterians*, from the famous nonconformist minister, Mr Richard Baxter, of the last century. The *Baxterians* have endeavoured to strike into a middle path between Calvinism and Arminianism, and to unite both these schemes. They profess to believe in the doctrines of election, effectual calling, and other tenets of Calvinism; and, consequently suppose, that a certain number, determined upon in the divine councils, will infallibly be saved. This they think necessary to secure the ends of Christ's interposition. But then, on the other hand, they reject the doctrine of reprobation, and admit, that our blessed Lord, in a certain sense, died for all; and that such a portion of grace is allotted to every man, as renders it his own fault if he doth not attain to eternal happiness. If he improves the common grace given to all mankind, this will be followed by that special grace which will end in his final acceptance and salvation. Whether the *Baxterians* are of opinion, that any, besides the elect, will actually make such a right use of common grace as to obtain the other and at length come to heaven, we cannot assuredly say. There may possibly be a difference of sentiment upon the subject, according as they approach nearer to Calvinism or Arminianism.

PREDETERMINATION, in philosophy and theology. The schoolmen call that concurrence of God, which makes men act, and determines them in all their actions both good and evil, *physical predetermination*, or *premotion*.

Divines hold, that God hath no part in sin, inasmuch as he only affords his concurrence to the physical part of human actions, not to the moral part.

Physical predetermination, or premotion, if there be any such thing, is that action of God, whereby he excites a second cause to act: or by which, antecedently to all operations of the creature, or before it could operate in consequence either of the order of nature or reason, he really and effectually moves and occasions it to produce all its actions: that is, whatever the creature does or acts, is really done and acted by the agency of God on the creature, who is all the time passive. So that, without such predetermination of God, all creatures must remain in an eternal state of inactivity; and, with such predetermination, it is impossible but that they should do what they are thus put upon doing.

Pringle.

It is strongly controverted, whether or no such a physical predetermination be necessary to the action of natural causes: the Scottists maintain the negative; urging, that all natural causes are of their own nature determined to a certain action; whence it should seem needless to call in a new predetermination of God, *e. gr.* to fire, to make it warm the hand. For if an object be, by the course of divine providence, applied to fire; what need a second application of the fire, to make it warm the object applied thereto; since beings are not to be multiplied unnecessarily.

And such predetermination some philosophers hold still less requisite to produce the acts of the will: at least, say they, the human mind must be allowed the common power and privilege of a second cause, and therefore be intitled to produce its own acts, as well as other strictly natural agents.

The Thomists, on the other hand, stand up strenuously for the physical predetermination: one of their principal arguments is drawn from the subordination of second causes to the first. Where there are several subordinate agents, say they, the lower agents do not act, unless first moved and determined thereto by the first; this being the very essence of subordination.

Again, the like they argue from the dominion of God over all his creatures: It is of the essence of dominion, say they, to apply and direct things subject thereto, to its own operations; and this, if the dominion be only moral, morally; but if it be also physical, physically. And that this is the case in respect of God and his creatures, is confessed.

PRESBYTERY, an assembly of the order of presbyters, or priests, with lay-elders, for the exercise of church-discipline.

The kirk, or church, of Scotland, is divided into 69 presbyteries, each consisting of a number of parishes, not exceeding 24, nor less than 12. The ministers of these parishes, with one ruling elder chosen half-yearly out of every kirk-session, constitute a presbytery; who, meeting in their chief town, whence the presbytery is denominated, choose a moderator, or, more properly, a prolocutor, who must be a minister, half-yearly.—They determine all appeals from kirk-sessions, *i. e.* from the several parochial assemblies; but can try nothing at the first instance cognizable before a kirk-session.—They compose all differences between ministers and people; for which end, they hold presbyterial visitations in each parish, where they examine the registers of the kirk-sessions, &c.—They inquire into repairs of churches; see that the glebe, &c. suffer no dilapidations; appoint schools in the parishes; and see that the funds be not misapplied. They alone can exclude from the communion; license probationers; suspend, depose, and, in effect, determine all ecclesiastical matters within their district. From the presbytery there lies an appeal, in all cases, to provincial synods.

PRINGLE (Sir John), an eminent physician and philosopher, was a younger son of Sir John Pringle of Stitchel, in the shire of Roxburgh, baronet; took the degree of M. D. at Leyden, 1730; and published there “*Dissertatio Inauguralis de Marcere Senili*,” 4to. After having been some years professor of moral philosophy at Edinburgh, he was in June 1745 appointed physician to the duke of Cumberland, and physician-general to the hospital of the forces in Flanders, where

the earl of Stair appears to have been his patron. In February 1746, Dr Pringle, Dr Armstrong, and Dr Barker, were nominated physicians to the hospital for lame, maimed, and sick soldiers, behind Buckingham-house; and in April 1749, Dr Pringle was appointed physician in ordinary to the king. In 1750 he published “*Observations on the Nature and Cure of Hospital and Gual Fevers, in a Letter to Dr Mead*,” 8vo (reprinted in 1755); and in 1752 he favoured the public with the result of his long experience in an admirable treatise under the title of “*Observations on the Disorders of the Army in Camp and Garrison*,” 8vo. On the 14th of April 1752, he married Charlotte, second daughter of Dr Oliver, an eminent physician at Bath. In 1756 he was appointed jointly with Dr Wintringham (now Sir Clifton Wintringham, bart.) physician to the hospital for the service of the forces of Great Britain. After the accession of his present majesty, Dr Pringle was appointed physician to the queen’s household, 1761; physician in ordinary to the queen in 1763, in which year he was admitted of the college of physicians in London; and on the 5th of June 1766, he was advanced to the dignity of a baronet of Great Britain. In 1772 he was elected president of the Royal Society, where his speeches for five successive years, on delivering the prize-medal of Sir Godfrey Copley, gave the greatest satisfaction. Sir John Pringle in 1777 was appointed physician-extraordinary to the king. He was also a fellow of the College of Physicians at Edinburgh, and of the Royal Medical Society at Paris; member of the Royal Academies at Paris, Stockholm, Gottingen, and of the Philosophical Societies at Edinburgh and Haerlem; and continued president of the Royal Society till November 1778; after which period he gradually withdrew from the world, and in 1781 quitted his elegant house in Pall Mall (where he had long distinguished himself as the warm friend and patron of literary men of every nation and profession), and made an excursion to his native country. He returned to London in the latter end of that year; died greatly beloved and respected Jan. 18, 1782; and having no children, was succeeded in estate and also (agreeably to the limitation of the patent) in title, by his nephew, now Sir James Pringle, bart. Among this worthy physician’s communications to the Royal Society, the following are the principal: 1. “*Some Experiments on Substances resisting Putrefaction*,” Phil. Trans. N° 495, p. 580; and N° 496, p. 525, 550; reprinted, with additions, in Martin’s Abridgment, vol. xi. p. 1365. 2. “*Account of some Persons seized with the Gual Fever by working in Newgate, and of the manner by which the Infection was communicated to one entire Family*,” vol. xlviii. p. 42. At the request of Dr Hales, a copy of this useful paper was inserted in the Gentleman’s Magazine, 1753, p. 71, before its appearance in the Transactions. 3. “*A remarkable Case of Fragility, Flexibility, and Dissolution of the Bones*,” Ib. p. 297. 4. “*Account of the Earthquakes felt at Brussels*,” vol. xlix. p. 546. 5. “*Account of sinking of a River near Pontypool, in Monmouthshire*,” Ib. p. 547. 6. “*Account of an Earthquake felt Feb. 18, 1756, along the coast of England, between Margate and Dover*,” Ib. p. 579. 7. “*Account of the Earthquake felt at Glasgow and Dumbarton; also of a Shower of*

Dust

Prophecy. Dust falling on a Ship between Shetland and Iceland," ib. p. 509. 8. "Several Accounts of the Fiery Meteor which appeared on Sunday, Nov. 26, 1758, between eight and nine at night," Vol. L. p. 218. 9. "Account of the Virtues of Soap in dissolving the Stone, in the Case of the Rev. Mr Matthew Simon," ib. p. 221. 10. "Account of the Effects of Electricity in Paralytic Cases," ib. p. 481. And see a letter to him on that subject from Professor Winthrop. "Some Account of the Success of the Vitrum Ceratum Antimonii" was printed in the "Edinburgh Medical Essays," Vol. V.

PROCELLARIA, (*Encycl*) See also Plate CCXLIII.

PROPHECY, a prediction made by divine inspiration.

One of the strongest evidences for the truth of revealed religion is that series of prophecies which is preserved in the Old and New Testaments; and a greater service, says an excellent writer, could not be done to Christianity than to lay together the several predictions of scripture with their completions, to show how particularly things have been foretold, and how exactly fulfilled. A work of this kind was desired by the lord Bacon, and he intitles it the "History of Prophecy;" in which he proposes, that every prophecy of the scripture be sorted with the event fulfilling the same throughout the ages of the world, both for the better confirmation of faith, and for the better illumination of the church touching those parts of prophecies which are yet unfulfilled; allowing, nevertheless, that latitude which is agreeable and familiar unto divine prophecies, being of the nature of the Author, with whom a thousand years are but as one day; and therefore they are not fulfilled punctually at once, but have springing and germinant accomplishment throughout many ages, though the height or fullness of them may refer to some one age. A work of this kind has been actually executed by the learned bishop Newton, in his *Dissertation on the Prophecies*.

With regard to the credibility of prophecy, it may be observed in general, that it is not at all incredible that God should upon special occasions foretell future events; and, if he affords an extraordinary revelation of his will to mankind, that he should attest its divine original by this kind of evidence; an evidence which, if the prophecies point to the events, and the events correspond with the prophecies, is in the highest degree conclusive and convincing. No previous conjecture nor accidental coincidence are sufficient to counteract and invalidate this kind of evidence.

As to most of the scripture-prophecies, they comprehend such a variety of particulars; they so minutely describe distant events, to be accomplished in circumstances which no human sagacity could foresee or conceive likely to occur; and they accord so exactly with the facts to which they refer; that there is no way of evading the conclusion, but by either denying the premises, that such prophecies were ever delivered and recorded, against which fact and history militate; or by pretending, that what we call predictions are only histories written after the events had happened, in a prophetic style and manner. But it is alleged in answer to this absurd plea, that there are all the proofs and authorities which can be had in cases of this na-

Prophecy. ture, that the prophets prophesied in one age, and that the events happened in another and subsequent age: and we have as much reason to believe these, as we have to believe any ancient matters of fact whatever; and by the same rule which leads us to deny these, we may as well controvert and contradict the credibility of all ancient history. But, besides, Christian writers undertake to prove the truth of prophecy, and consequently the truth of revelation, not by an induction of particulars long ago foretold and long ago fulfilled, the predictions of which may be supposed to have been written after the histories, but by instances of things which have confessedly many ages ago been foretold, and have in these later ages been fulfilled, or are fulfilling at this very time: so that there is no pretence for asserting such prophecies to have been written after the events; but it must be acknowledged, that the events many ages after, correspond exactly with the predictions many ages before. The evidence, therefore, which prophecy furnishes in favour of the truth of religion, is a growing evidence; and the more prophecies are fulfilled, the more testimonies there are and confirmations of the truth and certainty of divine revelation.

One of the greatest difficulties in Christianity turns upon the manner of completion of the scripture-prophecies. In the prophets of the Old Testament are frequent predictions of the Messiah, which the writers of the New frequently urge to the Jews and Heathens as fulfilled in Jesus Christ; and on this principle evince the truth of his mission. But these texts, thus urged from the Old, in the New Testament, are sometimes not to be now found in the Old; and at other times are not urged in the New in the literal and obvious sense which they seem to bear in the Old: whence most of the Christian commentators, divines, and critics, ancient and modern, judge them to be applied in a secondary, typical, allegorical, or mystical sense. Thus, *e. gr.* St Matthew, after an account of the conception of the Virgin and the birth of Jesus, says, "All this was done, that it might be fulfilled which was spoken by the prophet, saying, Behold, a virgin shall be with child, and shall bring forth a son, and they shall call his name Emmanuel." But the words, as they stand in Isaiah, whence they are supposed to be taken, do, in their obvious and literal sense, relate to a young woman who was to bring forth a child in the days of Ahaz; as appears from the context, and is owned by Grotius, Huetius, Cassalio, Curcellæus, Episcopius, Hammond, Simon, Le Clerc, Lamy, &c.

This prophecy, then, not being fulfilled in Jesus in the primary, literal, or obvious sense of the words, is supposed, like the other prophecies cited by the apostles, to be fulfilled in a secondary, typical, or allegorical sense: *i. e.* this prophecy, which was first literally fulfilled by the birth of the prophet's son in the time of Ahaz, was again fulfilled by the birth of Jesus, as being an event of the same kind, and intended to be signified either by the prophet, or by God who directed the prophet's speech. Grotius observes this to be the case in most, if not all, the prophecies and citations quoted from the Old in the New Testament: and Dodwell, with Sir John Marsham, refer even the famous prophecy in Daniel, about the seventy weeks,

Prophecy. to the time of Antiochus Epiphanes; showing, that the expressions taken thence by Christ, and urged by him as predicting the destruction of Jerusalem by the Romans, have only, in a secondary sense, a respect to that destruction.

And even that famous prophecy in the Pentateuch, "A prophet will the Lord God raise up unto thee, like unto me; to him shall ye hearken;" which St Luke refers to as spoken of Jesus Christ, is by Simon, Grotius, Stillingsfleet, &c. understood to signify, in its immediate sense, a promise of a succession of prophets.

It is allowed, then, the apostles applied the prophecies which they quote from the Old Testament, in a typical sense; but, unhappily, the rules whereby they quoted them are lost. Dr Stanhope laments the loss of the Jewish traditions or rules for interpreting scripture received among the rabbins, and followed by the apostles. But this loss Surenhusius, Hebrew professor at Amsterdam, thinks he has retrieved from the Jewish Talmud and the ancient Jewish commentaries; and has accordingly published to the world the rules whereby the apostles quoted the Old Testament. But the truth is, these rules are too precarious, strained, and unnatural, to gain much credit.

Mr Whiston condemns all allegorical explanation of the prophecies of the Old Testament cited in the New, as weak, enthusiastic, &c. and adds, that if a double sense of the prophecies be allowed, and there be no other method of showing their completion than by applying them secondarily and typically to our Lord, after having been in the first and primary intention long ago fulfilled in the times of the Old Testament, we lose all the real advantages of the ancient prophecies as to the proofs of Christianity.

He therefore sets up a new scheme in opposition thereto: he owns, that taking the present text in the Old Testament for genuine, it is impossible to expound the apostles citations of the prophecies of the Old Testament on any other than the allegorical foundation; and therefore, to solve the difficulty, he is forced to have recourse to a supposition contrary to the sense of all Christian writers before him, viz. that the text of the Old Testament has been greatly corrupted since the apostolic age by the Jews. His hypothesis is, that the apostles made their quotations out of the Old Testament rightly and truly from the Septuagint version, which in their time was in vulgar use, and exactly agreed with the Hebrew original; and that as they made exact quotations, so they argued justly and logically from the obvious and literal sense of the said quotations, as they then stood in the Old Testament; but that, since their times, both the Hebrew and Septuagint copies of the Old Testament have been so greatly corrupted, and so many apparent disorders and dislocations introduced therein, as to occasion many remarkable differences and inconsistencies between the Old and New Testament in respect to the words and sense of those quotations.

As to the manner wherein these corruptions were introduced, he says, the Jews, in the second century, greatly corrupted and altered both the Hebrew and Septuagint, especially in the prophecies cited by the apostles, to make their reasoning appear inconclusive: that, in the third century, they put into Origen's hand one of these corrupted copies of the Septuagint;

which Origen mistaking for genuine, inserted in his Hexapla, and thus brought into the church a corrupted copy of the Septuagint; and that, in the end of the fourth century, the Jews put into the hands of the Christians, who till then had been almost universally ignorant of the Hebrew, a corrupted copy of the Hebrew Old Testament.

Prophecy,
Provençal.

The disagreement, then, between the Old and New Testament, in respect to the said quotations, he contends, has no place between the genuine text of the Old Testament (now nowhere existing), but only between the present corrupted text of the Old and New Testament: and therefore, to justify the reasonings of the apostles, he proposes to restore the text of the Old Testament, as it stood before the days of Origen, and as it stood in the days of the apostles; from which text, thus restored, he doubts not, it will evidently appear, that the apostles cited exactly, and argued justly and logically, from the Old Testament. But this scheme of accomplishing prophecies labours under difficulties at least as great as the allegorical scheme. Its foundation is incredible, and its superstructure, from first to last, precarious. In effect, it is inconceivable that the Old Testament should be so corrupted; and it may even be made appear, that the Hebrew and Septuagint disagreed in the times of the apostles: add to this, that the means whereby he proposes to restore the true text will never answer that end; nor has he himself, from all the means he is yet possessed of, been able to restore one prophetic citation, so as to make that seem literally which before only seemed allegorically applied.

Upon this head it may be observed, that the double sense of prophecies, for which some have zealously contended, and which others have as strenuously opposed, ought not to be understood as if a prophecy equally and indifferently referred to many persons or events; or as if, literally referring to a lower person, it was only figuratively and allegorically to be interpreted of the Messiah, (for a passage only capable of being accommodated to him is not by any means a prediction of him): but it is to be so explained, as that it may appear the Messiah was principally intended, and the prophecy literally referred to him, though it might in part be applied to some other person; and might have been understood as referring to that inferior person alone, if farther light had not been thrown upon it by comparing other prophecies, or by the testimony of those whom on other accounts we have reason to regard as authentic interpreters. Nevertheless it must be acknowledged, that though the tracing of the Messiah in such prophecies as these may serve to illustrate the unity of design, which is a considerable additional proof of the truth of a revelation; yet the main stress is to be laid upon such prophecies as evidently and solely relate to the Messiah and his kingdom, rather than on those which are capable of reference to other persons or events.

PROVENÇAL POETS, in the History of Literature, a name given to certain professions of men who sprang up in Provence about the end of the 10th century, comprehending those that were called *Troubadours*, or *Trouverres*, *Jongleurs*, *Cantadours*, *Viellars*, and *Musars*, in whom the faculties both of music and poetry seemed to be united. The first of these were

Provençal,
Prudence.

so denominated from the art which they professed of inventing or finding out as well subjects and sentiments as rhymes, constituting what at that time was deemed poetry. The jongleurs are supposed to have taken their name from some mystical instrument on which they played, probably of a name resembling in its sound that by which their profession was distinguished: whence spring the jugglers, *quasi jocolatores*, as Menage conjectures, who went about fingering their verses in courts and the houses of noblemen, with a viol or harp, or other instrument, and were dressed in a peculiar habit, for the sake of entertaining, in a burlesque manner, their protectors and patrons. The cantadours, called also *chanterres*, were singers of songs and ballads, as were also the musari; and the violars were players on the viol.

All these arts were comprehended, in the French language, under the general denomination of *menestradie, menestraudise, et jongleire*.

The Provençal poets were not only the inventors and composers of metrical romances, songs, ballads and rhymes, to so great a number, and of such a kind, as to raise an emulation in most countries of Europe to imitate them; but, if we may credit the Italian writers, the best poets of Italy, namely Petrarch and Dante, owed much of their excellence to their imitation of the Provençals; and it is also said that the greater part of the novels of Boccace are taken from Provençal or ancient French romances. The learned Dr Percy, in his Essay on the Ancient English Minstrels, has given a very curious and satisfactory account of these fathers of modern poetry and music; and although he agrees that the several professions above enumerated were included under the general name of *minstrel*, he has in the notes to that essay, p. 42. with great accuracy assigned to each its distinct and peculiar office. Of the ancient writers of romance, a history is extant in the lives of the Provençal poets, written in French by J. Nostradamus, compiled and published at Lyons in 1575; but a much more satisfactory account of them is contained in the translation of this work into Italian, with many additions, by Gio. Mario de Crescimbeni, and published, in 1710, under the title of *Commentari Interni all Istoria della Volgare Poesia*.

PRUDENCE, in ethics, may be defined an ability of judging what is best, in the choice both of ends and means. According to the definition of the Roman moralist, Dr Officiis, lib. i. cap. 43. prudence is the knowledge of what is to be desired or avoided. Accordingly he makes *prudentia* (De Legibus, lib. i.) to be a contraction of *prudentia*, or foresight. Plato (De Legibus, lib. iii.) calls this the leading virtue; and Juvenal, Sat. x. observes,

Nullum nomen adest si sit prudentia.

The idea of prudence includes *cubania*, or due consultation, that is, concerning such things as demand consultation, in a right manner, and for a competent time, that the resolution taken up may be neither too precipitate nor too slow; and *consilium*, or a faculty of discerning proper means when they occur: and to the perfection of prudence, these three things are farther required, viz. *discretio*, or a natural sagacity; *acumen*, presence of mind, or a ready turn of thought; and *experientia*, or experience. The extremes of prudence are

Pulex,
Pitinus.

craft or cunning on the one hand, which is the pursuit of an ill end by direct and proper, though not honest means; and folly on the other, which is either a mistake, both as to the end and means, or prosecuting a good end by foreign and improper means.

PULEX, the FLEA, (*Encycl.*) This bloodthirsty insect, which fattens at the expence of the human species, prefers the more delicate skin of women; but preys neither upon epileptic persons, nor upon the dead or dying. It loves to nestle in the fur of dogs, cats, and rats. The nests of river-swallows are sometimes plentifully stored with them.

Fleas are apterous; walk but little, but leap to a height equal to 200 times that of their own body. This amazing motion is performed by means of the elasticity of their feet, the articulations of which are so many springs. Thus it eludes, with surprising agility, the pursuit of the person on whom it riots.—Through the microscope its form appears monstrous; and from observations made on the generation of fleas, we know them to be oviparous. The eggs, which are exceeding smooth and slippery, are deposited at the base of the hairs of animals, and on blankets, &c. In four or five days time, the egg, being hatched, produces a little nimble larva that feeds on greasy down. When touched, it rolls itself up into a ball. After it has crept for some time with great swiftness, it spins a small downy cocoon, which it is careful to keep in concealment. A fortnight after, it issues from its tomb, but leaping, and under the form of a flea. Among the memorabilia of fleas, one, they say, has been seen to draw a small silver piece of ordnance to which it was fastened, the firing of the gun nowise daunting its intrepidity. The owner carried it about in a little box lined with velvet, every now and then placing it on her arm to let it feed; but winter put an end to the being of this martial flea. Another flea that became slave to an Englishman, had, for its daily and easy task, to drag its golden chain and padlock, of the weight of one grain. A third flea served as a thill-horse to an English artist, who had made an ivory coach and six, that carried a coachman with his dog between his legs, a postillion, two footmen, and four insidè riders.—Mercurial ointment, brimstone, a fumigation with the leaves of penny-royal, or fresh-gathered leaves of that plant sewed up in a bag, and laid in the bed, are remedies pointed out as destructive of fleas.

PITINUS, a genus of insects belonging to the order of coleoptera. The antennæ are filiform: The last or exterior articulations are longer than the others: The thorax is nearly round, without a margin into which the head is drawn back or received: The feet are made for leaping. The most remarkable species are,

1. The *pectinicornis*. This is produced from a worm that lodges in wood and the trunks of trees, such as the willow, where it makes deep round holes, turns to a winged insect, takes flight, and roosts upon flowers. It is distinguished by its antennæ pectinated on one side, whence it has the name of *feathered*. The elytra and thorax are of a deep clay-coloured brown, the antennæ and legs are of a pale brown.

2. The *pertinax*. The form of this insect resembles the preceding one, saving that its antennæ are filiform.

Pyrometer.

Pyramids. It is all over of a deep blackish brown colour resembling foot. It attacks household-furniture, clothes, furs, and especially animals dried and preserved in collections of natural history, where it makes great havoc. When caught, this insect bends its legs, draws back its head, and lies as if it was dead till it thinks itself out of danger. It cannot be forced out of this state of inaction either by pricking or tearing; nothing but a strong degree of heat can oblige it to resume its motion and run away. There are many beautiful varieties of this genus; but they in general escape our attention by their minuteness, and living among hay, dried leaves, and divers other dusty matters, where they undergo their metamorphoses. The larvæ of some are found in trunks of decayed trees, in old tables, chairs, &c. See Plate CCCXX.

PYRAMIDS, (*Encycl.*) Dr Bryant has lately maintained, with considerable force of argument, this opinion, that the pyramids were designed for high altars and temples, and were constructed in honour of the Deity. If the chief pyramid was designed for a place of burial, what occasion, says he, was there for a well, and for passages of communication which led to other buildings? The apartments near the pyramids he supposes to be designed for the reception of priests, and to be appendages, not to a tomb, but to a temple of the Deity. The stone coffin, he apprehends, was a trough or reservoir for water, which by means of the well they drew from the Nile. The priests of Egypt delighted in obscurity, and they probably came by the subterraneous passages of the building to the dark chambers within; where they performed their lustrations, and other nocturnal rites. Many, he adds, of the ancient temples in this country were caverns in the rock, enlarged by art, and cut out into numberless dreary apartments; for no nation upon the earth was so addicted to gloom and melancholy as the Egyptians. From the top of the pyramids they observed the heavens, and marked the constellations; and upon the same eminence it is probable that they offered up vows and oblations.

PYROMETER, (*Encycl.*) Muschenbroek, who was the original inventor of this machine, has given a table of the expansion of the different metals, in the same degree of heat. Having prepared cylindric rods of iron, steel, copper, brass, tin, and lead, he exposed them first to a pyrometer with one flame in the middle; then with two flames; and successively to one with three, four, and five flames. But previous to this trial, he took care to cool them equally, by exposing them some time upon the same stone, when it began to freeze, and Fahrenheit's thermometer was at 32 degrees. The effects of which experiment are digested in the following table, where the degrees of expansion are marked in parts equal to the $\frac{1}{11750}$ part of an inch.

| Expansion of | Iron | Steel | Copper | Brass | Tin | Lead |
|--------------------------------------|------|-------|--------|-------|-----|------|
| By one flame | 80 | 85 | 89 | 110 | 153 | 155 |
| By two flames placed close together. | 117 | 123 | 115 | 220 | 274 | |

1

| Expansion of | Iron | Steel | Copper | Brass | Tin | Lead | Pyrometer. |
|----------------------------------------|------|-------|--------|-------|-----|------|------------|
| By two flames 2½ inches distant. | 109 | 94 | 92 | 141 | 219 | 263 | |
| By three flames placed close together. | 142 | 168 | 193 | 275 | | | |
| By four flames placed close together. | 211 | 270 | 270 | 361 | | | |
| By five flames | 230 | 310 | 310 | 377 | | | |

It is to be observed of tin, that it will easily melt when heated by two flames placed together. Lead commonly melts with three flames placed together, especially if they burn long.

From these experiments, it appears at first view, that iron is the least rarefied of any of these metals, whether it be heated by one more flames; and therefore is most proper for making machines or instruments which we would have free from any alterations by heat or cold, as the rods of pendulums for clocks, &c. So likewise the measures of yards or feet should be made of iron, that their length may be as nearly as possible the same, summer and winter.

The expansion of lead and tin, by only one flame, is nearly the same; that is, almost double of the expansion of iron. It is likewise observable, that the flames placed together, cause a greater rarefaction than when they have a sensible interval between them; iron, in the former case, being expanded 117 degrees, and only 109 in the latter; the reason of which difference is obvious.

By comparing the expansions of the same metal, produced by one, two, three, or more flames, it appears, that two flames do not cause double the expansion of one; nor three flames three times that expansion, but always less; and these expansions differ so much the more from the ratio of the number of flames as there are more flames acting at the same time.

It is also observable, that metals are not expanded equally at the time of their melting, but some more, some less. Thus tin began to run, when rarefied 219 degrees; whereas brass was expanded 377 degrees, and yet was far from melting.

Mr Ellicott found, upon a medium, that the expansion of bars of different metals, as nearly of the same dimensions as possible, by the same degree of heat, were as follows:

Gold, Silver, Brass, Copper, Iron, Steel, Lead,
73 103 95 89 60 56 149

The great difference between the expansions of iron and brass has been applied with good success to remedy the irregularities in pendulums arising from heat.

Mr Graham used to measure the minute alterations, in length, of metal bars, by advancing the point of a micrometer-screw, till it sensibly stopped against the end of the bar to be measured. This screw, being small and very lightly hung, was capable of agreement within the three or four-thousandth part of an inch. On this general principle Mr Smeaton contrived

46 D 2

his

Pyrometer. his pyrometer, in which the measures are determined by the contact of a piece of metal with the point of a micrometer-screw.

The following table shows how much a foot in length of each metal grows longer by an increase of heat corresponding to 180° of Fahrenheit's thermometer, or to the difference between freezing and boiling water, expressed in such parts of which the unit is equal to the 10000th part of an inch.

We shall close this article with a brief description of a pyrometer lately invented by M. De Luc, in consequence of a hint suggested to him by Mr Ramsden. The basis of this instrument is a rectangular piece of deal board two feet and a half long, 15 inches broad, and one inch and a half thick, and to this all the other parts are fixed. This is mounted in the manner of a table, with four deal legs, each a foot long and an inch and a half square, well fitted near its four angles, and kept together at the other ends by four firm cross-pieces. This small table is suspended by a hook to a stand; the board being in a vertical situation in the direction of its grain, and bearing its legs forward in such a manner as that the cross pieces which join them may form a frame, placed vertically facing the observer. This frame sustains a microscope, which is firmly fixed in another frame that moves in the former by means of grooves, but with a very considerable degree of tightness; the friction of which may be increased by the pressure of four screws. The inner sliding frame, which is likewise of deal, keeps the tube of the microscope in a horizontal position, and in great part without the frame, inasmuch that the end which carries the lens is but little within the space between the frame and the board. This microscope is constructed in such a manner as that the object observed may be an inch distant from the lens; and it has a wire which is situated in the focus of the glasses, in which the objects appear reversed. At the top of the apparatus there is a piece of deal, an inch and a half thick, and two inches broad, laid in a horizontal direction from the board to the top of the frame. To this piece the rods of the different substances, whose expansion by heat is to be measured, are sus-

ended: one end of it slides into a socket, which is cut in the thickness of the board; and the other end, which rests upon the frame, meets there with a screw, which makes the piece move backwards and forwards, to bring the objects to the focus of the microscope. There is a cork very strongly driven through a hole bored vertically through this piece; and in another vertical hole made through the cork, the rods are fixed at the top; so that they hang only, and their dilatation is not counteracted by any pressure. In order to heat the rods, a cylindrical bottle of thin glass, about 21 inches high, and four inches in diameter, is placed in the inside of the machine, upon a stand independent of the rest of the apparatus. In this bottle the rods are suspended at a little less than an inch distance from one of the sides, in order to have them near the microscope. Into this bottle is poured water of different degrees of heat, which must be stirred about, by moving upwards and downwards, at one of the sides of the bottle, a little piece of wood, fastened horizontally at the end of a kick: in this water is hung a thermometer, the ball of which reaches to the middle of the height of the rods. During these operations the water rises to the cork, which thus determines the length of the heated part; the bottle is covered, to prevent the water from cooling too rapidly at the surface; and a thin case of brass prevents the vapour from fixing upon the piece of deal to which the rods are fixed.

PYROPHORUS, (Encycl.) Mr Bewly prepares his pyrophorus in the following manner. "I fill, (says he) half or three-fourths of the bowl of a tobacco-pipe with a mixture, consisting of two parts of alum, previously calcined in a red-heat, and of powdered charcoal and salt of tartar each one part; pressing the matter down slightly, and filling the remainder of the bowl with fine sand. As soon as the powder becomes hot, the sand lying over it is put into a state of ebullition, which generally continues several minutes. This appearance seems to proceed partly from the vitriolic acid in the alum leaving its earth, and expelling fixed air from the alkali; while another part of it is possibly converted into vitriolic acid air. This phenomenon is succeeded by the appearance of a blue sulphureous flame, proceeding from the combination of the same acid with the phlogiston of the coal, and which continues about ten minutes or a quarter of an hour. After it ceases, no other remarkable appearance presents itself. The matter is now to be kept in a red-heat 20 minutes or half an hour; or it may continue there two hours longer, if the operator pleases, without any injury to the pyrophorus. The pipe being taken out of the fire, the matter is knocked out of it as soon as it becomes cool, and generally pretty soon afterwards takes fire spontaneously."

In another experiment, having added successively various and increasing quantities of fixed alkali to the salt heated as above, till the vitriolic acid contained in the mixture might be considered merely as an evanescent quantity, a pyrophorus was still produced on calcining it with charcoal as before. He also mixed equal parts of salt of tartar and vegetable or animal coal, or sometimes three parts of the former with two of the latter, and calcined them in the usual manner: and this composition, on being exposed to the air, generally

Pyropho-
rus,
Quartz.

nerally kindled in half a minute or a minute; though, as it contained no sulphur, it did not burn with so much vivacity as the vitriolic pyrophori. This, which Mr Bewly calls the *alkaline pyrophorus*, differs in no circumstance from M. De Suigney's neutral pyrophori, except in its not containing that principle to which he ascribes their accention. However, lest it might be suspected that the salt of tartar which he employed might accidentally contain vitriolated tartar, or vitriolic acid, he repeated the experiment with tartar calcined by himself, as well as with nitre fixed or alkali by deflagration with charcoal, and with iron filings; and in all these cases with the same result. By diversifying in a like manner M. De Suigney's experiments on the metallic pyrophori, Mr Bewly found that none of the three vitriols, heated with charcoal alone, in his usual method, could produce a pyrophorus. And thus he found that the addition of an alkaline salt to the composition, which was a part of M. De Suigney's process, was essential to its success.

Treating in the usual manner equal parts of calcined green vitriol and charcoal, the powder, which contained no sulphur nor hepar sulphuris, did not acquire any of the properties of a pyrophorus. The vitriolic acid seemed to have been entirely dissipated; having no bale to detain it, when dislodged from the metallic earth. The charcoal and calx of iron left in this process were calcined again, together with some salt of tartar; and a pyrophorus was produced, which exhibited indications of its containing a scarce perceptible portion of hepar sulphuris. Thirty grains of crocus martis astringens were calcined with 15 grains of charcoal, and the same quantity of salt of tartar; and the mixture burnt spontaneously, though it contained no hepar sulphuris or vitriolic acid. Having by these experiments evinced that metallic pyrophori may be prepared without vitriolic acid, Mr Bewly proceeded to form an aluminous pyrophorus of the same kind. For this purpose, he procured the earth of alum by a long and violent calcination; and examining a part of it, he found, by the usual tests, that it neither contained any sulphur, hepar sulphuris, nor alum undecomposed. This he considered as perfectly pure, though he afterwards found that it contained a small quantity of vitriolated tartar; and yet it repeatedly furnished a pyrophorus, as active as when alum itself is employed. From these and similar experiments, he infers, that the several kinds of pyrophori are not kindled by moisture, attracted by the vitriolic acid, as M. De Suigney has maintained: and his conclusion is farther confirmed by some experiments of Dr Priestley, from which it appears, that they are kindled in dry nitrous and dephlogisticated air.

M. Proust, cited by Mr Bewly, describes a variety of new pyrophori, which neither contain vitriolic acid, nor seem likely to owe their accention to the at-

traction of humidity from the air. These principally consist of a coaly matter simply divided by metallic or other earths; such are the sediment left on the filter in preparing Goulard's extract, various combinations of tartar, or its acid, or the acetic acid, with metals, calcareous earth, &c.

Mr Bewly, having evinced the insufficiency of M. De Suigney's theory, and discovered that the pyrophori are not kindled by moisture, attracted (merely) by the vitriolic acid, directed his attention to the nitrous acid, which Dr Priestley has shown to be a constituent part of atmospheric air, as the probable agent in the production of this phenomenon. The strong affinity which this acid has with phlogiston, and the heat, and even flame, which it is known to produce with certain inflammable matters, manifested that it was equal to the effect; and having excluded the vitriolic acid from having any essential concern in this operation, he suggests, either that the pyrophorus is kindled by moisture attracted by some of the other ingredients which compose it; or that it has the power of decomposing atmospheric air, by suddenly attracting its nitrous acid, and thereby generating a heat sufficient to kindle the phlogistic matter contained in it. This idea appeared plausible, when he farther considered that Dr Priestley produced the purest respirable air with this same acid combined with other principles; and that this as well as common air is diminished, and probably in part decomposed, in a variety of phlogistic processes. This ingenious writer concludes, upon the whole, from the experiments he hath made, that the pyrophorus seems to owe its singular property to its being a combination of earth or alkali with phlogiston; the vitriolic acid, when present, only occasionally increasing or diminishing the effect, according to circumstances. In the process of calcination, the earth or alkaline principle is not merely mixed, but actually, though loosely, combined with the phlogistic principle of the coal; so that the pyrophorus, considering it in its most simple state, is only a perfectly dry phlogisticated alkali or earth. On these data, the phenomena may be explained in the two following methods; with respect particularly to the influence of moisture and heat upon the pyrophorus. Supposing either the alkaline or earthy principle to have a greater affinity to water than to the phlogiston with which either of them is united, they may, on being exposed to a moist atmosphere, attract the humidity, and thereby set the phlogistic principle at liberty; which may, in its turn, attract, and be ignited by, the supposed aerial acid, its strong affinity to which is well known:—or, if this hypothesis be rejected, the inflammable matter may be kindled, merely in consequence of the heat produced by the combination of the alkali, &c. with moisture.

Pyropho-
rus,
Quartz.

Q.

QUARTZ, is a hard vitrifiable stone, something intermediate betwixt rock-crystals and flints, or opaque vitrifiable stones. Quartz is a stone well known by metallurgists, mineralogists, and miners, as it is frequently and abundantly found with ores, of which it often forms the matrix. It is also frequently

found where no ores are.—The most common quartz is more or less of a milky-white colour, and consequently semi-transparent. Some of them have various colours. This stone, which is very hard and very compact, is nevertheless cracked throughout its substance; to which also the rock-crystal is very liable, but

Quasia,
Red.

but much less than quartz. The fragments of quartz are always angular, and its internal surface has but little gloss. Quartz is a little waved, and has a greasy appearance. It is found not only of various colours, but also of various forms. It is frequently found crystallized in caverns and slits of rocks. Its crystallization is the same as that of rock-crystal. Quartz may be employed in vitrification, as all other vitrifiable stones are.

QUASIA, in botany, a genus of the monogynia order, belonging to the decandria class of plants. There is but one species, viz. the amara, or bitter-

ash, as it is called in the West Indies. It has of late come into great repute as a medicine, and the root is the part made use of. Its virtues were first revealed by a negro at Surinam, whose name was *Quassi*. This root appears to be the most pure and intense of all the bitters. At Surinam it has acquired a high character in curing intermittents, even in cases where the Peruvian bark has failed. It may be given in any form; but the most usual is an aqueous infusion, in the proportion of one drachm to a pint, the dose of which is one ounce.

Reproduction.

R.

RAGUSA, a city of Dalmatia, and capital of Ragusan. It is about two miles in circumference, and is pretty well built. It is strong by situation, having an inaccessible mountain on the land-side, and on the side of the sea a strong fort. It has an archbishop's see and a republic; and has a doge like that of Venice, but he continues only a month in office. It carries on a considerable trade with the Turks. E. Long. 18. 25. N. Lat. 42. 30.

RAPHIDIA, in zoology, a genus of insects, of the neuroptera order; the characters of which are these: The head is of a horny substance, and depressed or flattened: the mouth is armed with two teeth, and furnished with four palpi: the stemmata are three in number: the wings are deflected: the antennæ are filiform, as long as the thorax; the anterior part of which is lengthened out, and of a cylindrical form: the tail of the female is terminated by an appendix, resembling a flexible crooked bristle.—There are three species. The most remarkable is the ophiopsis; which for its shape is one of the most singular that can be seen †. It has an oblong head, shaped like a heart,

† See Plate
CCCXXI.

with its point joined to the thorax, and the broad part before. It is smooth, black, flattened, continually shaking, with short antennæ, yellowish maxillæ, and four palpi. Towards the middle of the upper part of the head, between the eyes, are the three stemmata, placed in a triangle. The thorax, to which this head is fastened, is narrow, long, and cylindrical. The abdomen, broader, is black like the rest of the body, with the segments margined yellow. The feet are of a yellowish cast. The wings, which are fatiguated, are white, diaphanous, veined, and as it were covered with a very fine net-work of black. This insect, for the figure of its head, resembles a snake. It is found but seldom, and in woods only. Its larva, chrysalis, and habitation, are absolutely unknown.

RED-BREAST, in ornithology, a species of MOTACILLA, under which article it was omitted. The bill is dusky; the forehead, chin, throat, and breast, are of a deep orange-colour; the head, hind part of the neck, the back, and tail, are of a deep ash-colour tinged with green; the wings rather darker, the edges inclining to yellow; the legs and feet dusky. This bird, though so very petulant as to be at constant war with its own tribe, yet is remarkably sociable with mankind: in the winter it frequently makes one of the family, and takes refuge from the inclemency of the season even by our fire-sides. Thomson has prettily described the annual visits of this guest; vide his *Winter*, l. 246. In the

spring this bird retires to breed in the thickest coverts, or the most concealed holes of walls and other buildings. The eggs are of a dull white, sprinkled with reddish spots. Its song is remarkably fine and soft; and the more to be valued, as we enjoy it the greatest part of the winter and early in the spring, and even through great part of the summer; but its notes are part of that time drowned in the general warble of the season. Many of the autumnal songsters seem to be the young cock red-breasts of that year.

RED-START, (*Motacilla phœniceus*), in ornithology, was omitted to be described under the article MOTACILLA, of which it is a species. This bird appears among us only in the spring and summer, and is observed to come over nearly at the same time with the nightingale. It makes its nest in hollow trees, and holes in walls and other buildings; which it forms with moss on the outside, and lines with hair and feathers. It lays four or five eggs, very like those of the hedge-sparrow, but rather paler, and more taper at the less end. This bird is so remarkably shy, that it will forsake its nest if the eggs are only touched. It has a very fine soft note; but, being a fullen bird, is with difficulty kept alive in confinement. It is remarkable in shaking its tail; it moves it horizontally, as a dog does when fawning.—The bill and legs of the male are black; the forehead white; the crown of the head, hind part of the neck, and the back, are of a deep blue-grey; the cheeks and throat black; the breast, rump, and sides are red; the two middle feathers of the tail brown, the others red; the wings brown. In the female, the top of the head and back are of a deep ash-colour; the rump and tail of a duller red than those of the male; the chin white; the lower side of the neck cinereous; the breast of a paler red.

REPRODUCTION, (*Encecl.*) By reproduction is usually understood the restoration of a thing before existing, and since destroyed. It is very well known that trees and plants may be raised from slips and cuttings; and some late observations have shown, that there are some animals which have the same property. The polype was the first instance we had of this; but we had scarce time to wonder at the discovery Mr Trembley had made, when Mr Bonett discovered the same property in a species of water-worm. Amongst the plants which may be raised from cuttings, there are some which seem to possess this quality in so eminent a degree, that the smallest portion of them will become a complete tree again.

It deserves inquiry, whether or not the great Author

Reproduction. thor of nature, when he ordained that certain insects, as these polypes and worms, should resemble those plants in that particular, allowed them this power of being reproduced in the same degree; or, which is the same thing, whether this reproduction will or will not take place in whatever part the worm is cut. In order to try this, Mr Bonett entered on a course of many experiments on the water-worms which have this property. These are, at their common growth, from two or three inches long, and of a brownish colour, with a cast of reddish. From one of these worms he cut off the head and tail, taking from each extremity only a small piece of a twelfth of an inch in length; but neither of these pieces were able to reproduce what was wanting. They both perished in about 24 hours; the tail first, and afterwards the head. As to the body of the worm from which these pieces were separated, it lived as well as before, and seemed indeed to suffer nothing by the loss, the head-part being immediately used as if the head was thereon, boring the creature's way into the mud. There are, besides this, two other points in which the reproduction will not take place; the one of these is about the fifth or sixth ring from the head, and the other at the same distance from the tail; and in all probability the condition of the great artery in these parts is the cause of this.

What is said of the want of the reproductive power of these parts relates only to the head and tail ends; for as to the body, it feels very little inconvenience from the loss of what is taken off, and very speedily reproduces those parts. Where, then, does the principle of life reside in such worms, which, after having their heads cut off, will have not only the same motions, but even the inclinations, that they had before? and yet this difficulty is very small, compared to several others which at the same time offer themselves to our reason. Is this wonderful reproduction of parts only a natural consequence of the laws of motion? or is there lodged in the body of the creature a chain of minute buds or shoots, a sort of little embryos, already formed and placed in such parts where the reproductions are to begin? Are these worms only mere machines? or are they, like more perfect animals, a sort of compound, the springs of whose motions are actuated or regulated by a sort of soul? And if they have themselves such a principle, how is it that this principle is multiplied, and is found in every separate piece? Is it to be granted, that there are in these worms, not a single soul (if it is to be so called) in each, but that each contains as many souls as there are pieces capable of reproducing perfect animals? Are we to believe with Malpighi, that these sorts of worms are all heart and brain from one end to the other! This may be; but yet if we knew that it was so, we should know in reality but very little the more for knowing it: and it seems, after all, that in cases of this kind we are only to admire the works of the great Creator, and sit down in silence.

The nice sense of feeling in spiders has been much talked of by naturalists; but it appears that these worms have yet somewhat more surprising in them in regard to this particular. If a piece of flick, or any other substance, be brought near them, they do not stay for its touching them, but begin to leap and frisk about as soon as it comes towards them. There want, however, some farther experiments to ascertain whe-

ther this be really owing to feeling or to sight; for though we can discover no distinct organs of sight in these creatures, yet they seem affected by the light of the sun or a candle, and always frisk about it in the same manner at the approach of either; nay, even the moon-light has some effect upon them.

A twig of willow, poplar, or many other trees, being planted in the earth, takes root, and becomes a tree, every piece of which will in the same manner produce other trees. The case is the same with these worms: they are cut to pieces, and these several pieces become perfect animals; and each of these may be again cut into a number of pieces, each of which will in the same manner produce an animal. It had been supposed by some that these worms were oviparous: but Mr Bonett, on cutting one of them to pieces, having observed a slender substance, resembling a small filament, to move at the end of one of the pieces, separated it; and on examining it with glasses, found it to be a perfect worm, of the same form with its parent, which lived and grew larger in a vessel of water into which he put it. These small bodies are easily divided, and very readily complete themselves again, a day usually serving for the production of a head to the part that wants one; and, in general, the smaller and slenderer the worms are, the sooner they complete themselves after this operation. When the bodies of the large worms are examined by the microscope, it is very easy to see the appearance of the young worms alive, and moving about within them: but it requires great precision and exactness to be certain of this; since the ramifications of the great artery have very much the appearance of young worms, and they are kept in a sort of continual motion by the systoles and diastoles of the several portions of the artery, which serve as so many hearts. It is very certain, that what we force in regard to these animals by our operations, is done also naturally every day in the brooks and ditches where they live. A curious observer will find in these places many of them without heads or tails, and some without either; as also other fragments of various kinds, all which are then in the act of completing themselves: but whether accidents have reduced them to this state, or they thus purposely throw off parts of their own body for the reproduction of more animals, is not easy to determine. They are plainly liable to many accidents, by which they lose the several parts of their body, and must perish very early if they had not a power of reproducing what was lost: they often are broken into two pieces, by the resistance of some hard piece of mud, which they enter; and they are subject to a disease, a kind of gangrene, rotting off the several parts of their bodies, and must inevitably perish by it, had they not this surprising property.

This worm was a second instance, after the polype, of the surprising power in an animal of recovering its most essential parts when lost. But nature does not seem to have limited her beneficence in this respect to these two creatures. Mr Bonett tried the same experiments on another species of water-worm, differing from the former in being much thicker. This kind of worm, when divided in the summer-season, very often shows the same property: for if it be cut into three or four pieces, the pieces will lie like dead for a long time, but afterwards will move about again; and will be found in this state of rest to have recovered a head,

or a tail, or both. After recovering their parts, they move very little; and, according to this gentleman's experiments, seldom live more than a month.

It should seem, that the more difficult success of this last kind of worm, after cutting, and the long time it takes to recover the lost parts, if it do recover them at all, is owing to its thickness; since we always find in that species of worms which succeeds best of all, that those which are thinnest always recover their parts much sooner than the others.

The water-insects also are not the only creatures which have this power of recovering their lost parts. The earth affords us some already discovered to grow in this manner from their cuttings, and these not less deserving our admiration than those of the water: the common earth-worms are of this kind. Some of these worms have been divided into two, others into three or four pieces; and some of these pieces, after having passed two or three months without any appearance of life or motion, have then begun to reproduce a head or tail, or both. The reproduction of the anus, after such a state of rest, is no long work; a few days do it: but it is otherwise with the head, that does not seem to perform its functions in the divided pieces till about seven months after the separation. It is to be observed, that in all these operations both on earth and water-worms, that the hinder part suffers greatly more than the fore part in the cutting; for it always twists itself about a long time, as if actuated by strong convulsions; whereas the head usually crawls away without the appearance of any great uneasiness.

The reproduction of several parts of lobsters, crabs, &c. makes also one of the great curiosities in natural history. That, in lieu of an organical part of an animal broken off, another shall rise perfectly like it, may seem inconsistent with the modern system of generation, where the animal is supposed to be wholly formed in the egg. Yet has the matter of fact been well attested by the fishermen, and even by several virtuosos who have taken the point into examination, particularly M. de Reaumur and M. Perrault, whose skill and exactness in things of this nature will hardly be questioned. The legs of lobsters, &c. consist each of five articulations: now, when any of the legs happen to break by any accident, as in walking, &c. which frequently happens, the fracture is always found to be in a part near the fourth articulation; and what they thus lose is precisely reproduced in some time afterwards; that is, a part of a leg shoots out, consisting of four articulations, the first whereof has two claws as before; so that the loss is entirely repaired.

If a lobster's leg be broken off by design at the fourth or fifth articulation, what is thus broken off always comes again; but it is not so if the fracture be made in the first, second, or third articulation. In those cases, the reproduction is very rare if things continue as they are. But what is exceedingly surprising is, that they do not; for, upon visiting the lobster maimed in these barren and unhappy articulations, at the end of two or three days, all the other articulations are found broken off to the fourth; and it is suspected they have performed the operation on themselves, to make the reproduction of a leg certain.

The part reproduced is not only perfectly like that retrenched, but also, in a certain space of time, grows

equal to it. Hence it is that we frequently see lobsters, which have their two big legs unequal, and that in all proportions. This shows the smaller leg to be a new one.

A part thus reproduced being broken, there is a second reproduction. The summer, which is the only season of the year when the lobsters eat, is the most favourable time for the reproduction. It is then performed in four or five weeks; whereas it takes up eight or nine months in any other season.

The small legs are sometimes reproduced, but more rarely, as well as more slowly, than the great ones: the horns do the same. The experiment is most easily tried on the common crab.

REST-HARROW, or CAMMOCK, the *Ononis Arvensis*. A decoction of this plant has been much recommended to horses labouring under a stoppage of urine. It is the pest of some corn-fields; but in its younger state, before the plant has acquired its thorns, it is a most acceptable food to sheep.

ROSYCRUCIANS, ROSICRUCIANS, or *Brothers of the Rosy Cross*, a name assumed by a sect or cabal of hermetical philosophers, who appeared, or at least were first taken notice of, in Germany, in the beginning of the 16th century. They pretended to be masters of all sciences, and to have many important secrets, particularly that of the philosopher's stone.—Their society is frequently denoted by the abbreviations F. R. C.

ROUSSEAU (John James), a celebrated philosopher, was the son of a watchmaker at Geneva, and was born in 1712. In the early part of his life he embraced the Roman Catholic religion, and travelled into Italy. Some time after, he went into France; and was secretary to M. de Montaigu ambassador at Venice in 1743. Till he was 40 years of age he remained entirely unknown in the literary world. His Discourse against the Sciences, which in 1750 was honoured with the prize by the academy of Dijon, first drew him from this obscurity. Though the subject had formerly been treated by the famous Henry Cornelius Agrippa, Rousseau gave his subject all the charms of novelty; displaying the most uncommon resources of genius and knowledge. A variety of writers attacked his opinion; dispute on dispute ensued, and he found himself engaged in the most formidable lists of literary controversy. His discourse on the Inequality among Men and of the Origin of Society, tho' it supports a false system, is yet done with admirable art; and this performance, especially its dedication to the Republic of Geneva, are among those master-pieces of eloquence, of which the ancients alone have given us any idea. His Letter to M. d'Alembert on the Project of establishing a Theatre at Geneva, published in 1757, contains, amidst many paradoxes, some of the most important truths. This letter, in which he decries the stage, was the source of an irreconcilable enmity between him and the celebrated Voltaire. However, it is remarkable, that even Rousseau, this enemy of plays, wrote a comedy, and presented a Pastoral to the theatre; the poetry and music of which he composed with the most pleasing attention to the simplicity of rural sentiment and manners. The author, who had an excellent talent for music, had cultivated it from his infancy with equal taste; and his Dictionary of Music is one of the best works of the kind. His Epistolary Romance, to which

which the English translator had given the name of *Eloïsa*, is universally known; but of all the works of this celebrated writer, his *Emilius*, or *Treatise on Education*, made the greatest noise. The most exceptionable part of this work is the third volume; which is almost full of objections to Christianity. This proved fatal to his repose. He had lived from the year 1754 in a country house near Montmorenci; a retreat which he owed to the generosity of a farmer-general of the revenues. The parliament of Paris condemned the last-mentioned work in 1762, and commenced a criminal process against the author, which obliged him to fly from that city. Being proscribed also in his native place, he at length found an asylum in Switzerland in the sovereignty of Neuchâtel. His first care was to defend his *Emilius* against the anathemas of the archbishop of Paris. His "Letters from the Mountains" were published soon after; but this book, less eloquent than his "Letter to the archbishop of Paris," and filled with uninteresting invectives against the magistrates and ecclesiastics of Geneva, irritated the Protestant ministers without reconciling him to the Romish clergy.

In the year 1753, Rousseau had solemnly abandoned the Romish religion; and, what is remarkable, at the very time that he had determined to reside in a Catholic country. This conversion, however, could not regain the esteem of the Protestant teachers; nor could the protection of the king of Prussia secure him against the vengeance of the minister of the village where he resided. He therefore took the resolution of visiting England; but here he soon embroiled himself with the celebrated Mr Hume, by whose means he had been placed in an agreeable retreat in Derbyshire, and who had obtained for him a pension from the king. He again returned to France, where his patrons obtained leave for him to reside in Paris, but on condition that he should not write any thing on the subjects of religion or government. He obeyed this injunction inviolably, and wrote nothing on any subject, but contented himself with the peaceful life of a philosopher. In May 1776 he accepted the invitation of the marquis and marchioness de Girardin, who had prepared a neat little house for him at a small distance from their delightful castle of Ermenonville, about 30 miles from Paris. This retreat was perfectly conformable to the wishes of Rousseau. Every day he amused himself in a neighbouring wood in collecting plants for his herbar. The marquis, who was himself a philosopher, indulged his passion for rural life, and was enamoured with the writings of the singular Rousseau. They had musical parties frequently, at which he assisted; and he composed several airs in all that simple style of nature for which he had ever been remarked. Among others he set several passages of our Shakespeare to music, and played them himself on the forte piano in the most enchanting manner.—In this sweet retirement he lived two years in the most agreeable manner; and died on the 2d of July 1778, in the 66th year of his age. The marquis has since erected a sepulchral monument, to cover the remains of his departed friend. This mausoleum is constructed of white marble, with the bust of the deceased by Houdon; and its decorations are in the best taste. One of its sides exhibits two doves, for *Eloïsa*; another, a mother sucking her child, for *Emilius*; a third, children sacrificing on the

altar of nature; and the fourth, a lyre, with other symbols of poetry and music. The inscription on the monument is long; and contains a pompous encomium on the genius, sentiments, and moral character of Mr Rousseau.

We shall conclude the life of this singular man with the character of himself and of his writings, as delivered by the masterly pen of Dr Beattie. "I consider Rousseau," says the Doctor, "as a moral writer of true genius. Sensibility of heart; a talent for extensive and accurate observation; liveliness and ardour of fancy; and a style, copious, nervous, and elegant, beyond that of any other French writer; are his distinguishing characteristics. In argument he is not always equally successful; for he often mistakes declamation for proof, and hypothesis for fact; but his eloquence, when addressed to the heart, overpowers with force irresistible. A greater number of important facts relating to the human mind are recorded in his works, than in all the books of all the sceptical philosophers ancient and modern. And he appears in general to be a friend to virtue, to mankind, to natural religion, and sometimes to Christianity. Yet none even of his best works are free from absurdity. His reasonings, on the effects of the sciences, and on the origin and progress of human society, are diffuse, inaccurate, and often weak; much perverted by theories of his own, as well as by too implicit an admittance of the vague assertions of travellers, and of the systems and doctrines of some favourite French philosophers. And he seems, in these, and frequently too in his own writings, to consider animal pleasure, and bodily accomplishments, as the happiness and perfection of man. His plan of education, though admirable in many parts, is in some injudicious and dangerous, and impracticable as a whole. The character of Julia's lover is drawn with a masterly hand indeed, and well conducted throughout; but the lady has two characters, and those incompatible. The wife of Wolmar is quite a different person from the mistress of St Prieux. Wolmar himself is an impossible character; destitute of principle, yet of rigid virtue; destitute of feeling, yet capable of tenderness and attachment; delicate in his notions of honour, yet not ashamed to marry a woman whom he knew to be to all intents and purposes devoted to another. Some of this author's remarks on the spirit of Christianity, and on the character of its Divine Founder, are not only excellent, but transcendently so; and I believe no Christian can read them without feeling his heart warmed, and his faith confirmed. But what he says of the absurdities which he fancies to be contained in the Sacred History, of the impropriety of the evidence of miracles, of the analogy between those of Jesus Christ and the tricks of jugglers, of the insignificance and impertinence of prayer, of the sufficiency of human reason for discovering a complete and comfortable scheme of natural religion, of the discouraging nature of the terms of salvation offered in the Gospel, of the measure of evidence that ought to accompany Divine Revelation (which, as he states it, would be incompatible with man's free agency and moral probation); what he says of these, and several other theological points of great importance, betrays a degree of ignorance and prejudice, of which, as a philosopher, as a scholar, and as a man,

man, he should have been utterly ashamed. He appears to be distressed with his doubts; and yet, without having ever examined whether they be well or ill founded, scruples not to exert all his eloquence on purpose to infuse them into others: a conduct which I must ever condemn as illiberal, unjust, and cruel. Had Rousseau studied the Scripture, and the writings of rational divines, with as much care as he seems to have employed in reading the books, and listening to the conversation of French infidels, and in attending to the unchristian practices and doctrines warranted by some ecclesiastical establishments; I may venture to assure him, that his mind would have been much more at ease, his works much more valuable, and his memory much dearer to all good men. Rousseau is, in my opinion, a great philosophical genius, but wild, irregular, and often self-contradictory; disposed, from

the fashion of the times, and from his desire of being reputed a bold speaker and free-thinker, to adopt the doctrines of infidelity; but of a heart too tender, and an imagination too lively, to permit him to become a thorough-paced infidel. Had he lived in an age less addicted to hypothesis, he might have distinguished himself as a moral philosopher of the first rank.—To conclude, the writings of this author, with all their imperfections, may be read by the philosopher with advantage, as they often direct to the right observation and interpretation of nature; and by the Christian, without detriment, as the cavils they contain against religion are too slight and too paradoxical to weaken the faith of any one who is tolerably instructed in the principles and evidences of Christianity. To the man of taste they can never fail to recommend themselves, by the irresistible charms of the composition.²⁶

S.

SAINTS, (*Encycl.*) Cardinal Bellarmine, and other

Papish writers, have pleaded, that by praying to the saints, they only intend to express a desire of their intercession, and that their invocation of the saints terminates ultimately in God. Accordingly they have distinguished two sorts of worship; one called *latría*, appropriate to God; and another *dulia*, which, being of an inferior nature, is paid to angels and saints. However, many of their own writers have exploded this distinction, and others have owned that it is unscriptural. There is another sort of worship, which is of a higher degree than that paid to saints in common, and which is peculiar to the Virgin Mary: this they call *hyperdulia*.

After all, those who read their books of devotion, their Hours, their Offices, their Rosaries, their Breviaries, and their Missals, will find many direct addresses to the saints, which are very different from those prayers whose object is merely to supplicate their intercession. Besides, the council of Trent, sess. 25. directs to apply to the saints for their help and assistance, as well as their prayers; and condemns all who think that it is not good and profitable to offer prayers to saints, as chargeable with impious sentiments. And the creed of pope Pius IV. expressly insists upon it as an article of faith, that the saints reigning together with Christ are to be invoked. As to the antiquity of this practice, the council of Trent, sess. 25. speaks of it as the usage of the apostolic and catholic church from the beginning of Christianity. As to the doctrine of the intercession of saints and angels, there is not the least intimation of it in the writings of the two first centuries; though it must be allowed to have been introduced in the next century, and that Origen and Cyprian expressly favour this superstition. The worship of saints and angels is of a much later date, especially as a standing generally-received doctrine of the church. For though Athanasius was for worshipping the saints, yet Cyril, who lived in the next century, says, We neither call the holy martyrs gods, nor are we used to worship them. St Austin affirms, that neither saints nor angels will be worshipped. Archbishop Usher says, that as to the first 400 years after Christ, for nine parts of that time, not one true testimony can be produced out of any father in favour of this doctrine; and cardinal Perron,

Richlieu, and other learned writers among the Romanists, own, that the invocation of saints was not practised for the three first centuries. The first symptoms of this worship did not appear till towards the end of the fourth century, and it seems to have sprung out of the regard which the Christians at that time manifested to the memory of the martyrs. They frequented their tombs, and erected altars there, praying to God, and engaging themselves to a strict imitation of the virtues and piety of the departed martyrs: by degrees this veneration degenerated into praises and eulogiums of the saints themselves, in which they used some apotrophes and rhetorical addresses; whence proceeded a superstitious regard to them, and at length a direct invocation and worship of them. Nor does it appear, that any public prayers to saints were established till A. D. 788, by the second council of Nice; and this council was condemned by another held at Francfort, A. D. 794; and the invocation of saints was likewise condemned by a former council held at Constantinople, A. D. 755, consisting of 388 bishops. In the seventh century, Gregory expressly says, that angels refused to be worshipped since the appearance of Christ.

In order to convey some idea of the extravagance to which veneration for reputed saints hath arrived in the Romish church, we shall only mention one instance out of many that might be alleged. It is well known that there were three altars in the cathedral church of Canterbury, one erected to the honour of Christ, another to the Virgin Mary, and a third to St Thomas a Becket; and the offerings at his shrine amounted to 1000*l.* when those to the Virgin did not amount to 5*l.* and those to Christ were nothing; and Rapin informs us, that in one year, viz. A. D. 1420, there were no less than 50,000 foreigners who came in pilgrimages to pay their homage at this tomb.

SALT, (*Encycl.*) See also **ACIDS** and **ALKALIES** in this **APPENDIX**.—Acids and alkalies, and combinations of both, when in a concrete form, are salts, and of the purest sort. The bodies, therefore, to which the name of *salts* more properly belongs, are the concretions of those substances; which are accordingly called *acid salts*, *alkaline salts*, and *neutral salts*. These last are combinations of acid and alkaline salts, in such proportion

proportion as to render the compounds neither four nor alkaline to the taste. This proportionate combination is called *saturation*: thus the common kitchen-salt is a neutral salt, composed of marine acid and mineral alkali combined together to the point of saturation. The appellation of *neutral salts* is also extended to denote all those combinations of acids, and any other substance with which they can unite, so as to lose, wholly or in great measure, their acid properties.

Notwithstanding that the general definition of salts given above is commonly received, yet there are many writers, especially mineralogists, who confine the denomination of *salts* to those substances only which, besides the general properties of salts, have the power of crystallizing, that is, of arranging their particles so as to form regularly-shaped bodies, called *crystals*; when the water superfluous to their concrete existence has been evaporated.

Salts of various sorts are found already formed in nature, but a great many others are made by art, and even several of the natural ones may be imitated. We shall only consider those salts, either natural or artificial, which are mostly used.

The vitriolic acid, when combined with other substances, forms vitriolic salts, which vary both in specific names and properties, according to the various substances with which the acid is combined. Thus the vitriolic acid, combined with mineral alkali, forms the salt called *Glauber's salt*, or *sal mirabile*. When it is combined with calcareous earths, it forms vitriolic salts with bases of calcareous earth, which are commonly called *salenites*. When combined with argillaceous earths, it forms alum. When combined with metals, it forms vitriolic salts with metallic bases, to which the general name *vitriols* is given; and in commerce are commonly called *copperas*. The vitriols principally used are, 1. The martial vitriol; called also *English vitriol*, *green vitriol*, or *green copperas*, which is a combination of vitriolic acid with iron. 2. The vitriol of copper, called also *blue vitriol*, *Cyprian vitriol*, or *blue copperas*; which is a combination of vitriolic acid and copper. 3. The vitriol of zinc, called also *white copperas*, and *Goslar vitriol*; which is a combination of the same acid with a semi-metal called *zinc*. It is a property peculiar to the vitriolic acid, that all the combinations of it, with those substances with which it can form neutral salts, are susceptible of crystallization.

The nitrous acid, combined with all the substances with which it can mix, forms saline substances, in general called *nitrous salts*; specifying each particular salt by the name of the substance united to the acid. Thus nitrous acid, with fixed vegetable alkali, forms a saline substance called *nitre*, or *saltpetre*. With mineral alkali, forms cubic or quadrangular nitre. When mixed with metallic substances, forms metallic nitrates, which are specified *nitre of gold*; *nitre of silver*, or *lunar nitre*, *lunar crystals*, and *crystals of silver*, *nitrous crystals of mercury*; *nitre of copper*, &c.

The marine acid, combined with various matters, forms marine salts, or simply salts, specified by the names of their particular bases. The sea-salt, or kitchen salt, and sal gem, are combinations of marine acid and mineral alkali. When this acid is combined with

volatile alkali, it forms sal ammoniac (A). With metals it forms metallic salts, called *salt of gold*, *salt of copper*, &c. according to the various metals combined with the acid. The salt of silver is also called *luna cornea*; the salt of lead is often called *plumbum corneum*; and the salts of antimony, and of arsenic, are known by the names of *butter of antimony*, and *butter of arsenic*.

The acid of tartar (the purest part of which, or that saline substance which first crystallizes, by evaporation, in the vessels in which it is purified, is called *cream of tartar*), and also all other concrete vegetable acids analogous to it, when mixed with various other substances, form compounds, generally called *tartareous salts*, or *soluble tartars*, because they are dissolved by water more easily than the acid of tartar itself.

Acetous salts, that is, all salts containing the acid of vinegar, are also combined with various bases, and form saline substances of different names; the principal of which are, the acetous salt of copper, called *crystals of Venus*, or of *verdigrise*, by the chemists, and *distilled or crystallized verdigrise* in commerce; the acetous salt of lead, commonly called *salt or sugar of lead*; and the acetous mercurial salts.

Sugar is an essential vegetable salt, of a pleasant sweet taste, containing a vegetable acid combined with earth and oil.

Potash is a fixed vegetable alkali, extracted from the ashes of wood. Concrete volatile alkalies are generally called *volatile salts*; although this name is sometimes also given to the volatile salt of amber, which is not an alkaline, but an acid salt.

Borax is a neutral saline matter, whose origin, whether animal or vegetable, is as yet unknown, its components being not sufficiently examined. It is soluble in water, and very nearly as crystallizable as alum. When borax is exposed to the fire, it first bubbles and foams very much, but afterwards it melts into a clear glass. When acids are combined with the alkaline part of borax, a substance of a singular nature is separated from it, commonly called *sedative salt*. Altho' this substance acts as an acid in borax, by saturating its alkali, yet it has no acid taste, nor doth it turn the tincture of heliotropium to a red, as other acids do. It is the property of borax to facilitate considerably the fusion of metals, of earths, and other minerals. Some species of stones and earths cannot be vitrified at all, except they are mixed with borax. For this property borax is commonly used as a flux (that is, a substance which facilitates the fusion of other bodies) in various manufactories; but especially in soldering metals, and in assaying ores.

Phosphoric salts are combinations of alkaline, earthy, and metallic substances with the acid obtained from the phosphorus of urine.

Besides the above-mentioned salts, there are several others to be met with in the writings of the chemical and medical authors; but, as they are of little consequence, we shall omit any account of them.

SANDEMANIANS, in ecclesiastical history, a modern sect that originated in Scotland about the year 1728; where it is at this time distinguished by the name of *Glassites*, after its founder Mr John Glass, who was a minister of the established church in that

46 E 2 king-

(A) Ammoniacal salts is also a general name given to all neutral salts composed of an acid saturated with a volatile alkali.

Sandema-
nians.Sapota
Sassafras.

kingdom; but being charged with a design of subverting the national covenant, and sapping the foundation of all national establishments by the kirk judicatory, was expelled by the synod from the church of Scotland. His sentiments are fully explained in a tract published at that time, intitled, "The Testimony of the King of Martyrs," and preserved in the first volume of his works. In consequence of Mr Glas's expulsion, his adherents formed themselves into churches conformable in their institution and discipline to what they apprehended to be the plan of the first churches recorded in the New Testament. Soon after the year 1755, Mr Robert Sandeman, an elder in one of these churches in Scotland, published a series of letters addressed to Mr Hervey, occasioned by his Theron and Asaph; in which he endeavours to show, that his notion of faith is contradictory to the scripture account of it, and could only serve to lead men, professedly holding the doctrines commonly called *Calvinistic*, to establish their own righteousness upon their frames, inward feelings, and various acts of faith. In these letters Mr Sandeman attempts to prove, that faith is neither more nor less than a simple assent to the divine testimony concerning Jesus Christ, recorded in the New Testament; and he maintains, that the word *faith*, or *belief*, is constantly used by the apostles to signify what is denoted by it in common discourse, viz. a persuasion of the truth of any proposition, and that there is no difference between believing any common testimony, and believing the apostolic testimony, except that which results from the nature of the testimony itself. This led the way to a controversy, among those who were called *Calvinists*, concerning the nature of justifying faith; and those who adopted Mr Sandeman's notion of it, and who took the denomination of *Sandemanians*, formed themselves into church order, in strict fellowship with the churches in Scotland, but holding no kind of communion with other churches. The chief opinions and practices in which this sect differs from other Christians, are, their weekly administration of the Lord's Supper; their love-feasts, of which every member is not only allowed but required to partake, and which consist of their dining together at each other's houses in the interval between the morning and afternoon service; their kiss of charity used on this occasion, at the admission of a new member, and at other times, when they deem it to be necessary or proper; their weekly collection before the Lord's Supper, for the support of the poor, and defraying other expenses; mutual exhortation; abstinence from blood and things strangled; washing each other's feet, the precept concerning which, as well as other precepts, they understand literally; community of goods, so far as that every one is to consider all that he has in his possession and power as liable to the calls of the poor and church, and the unlawfulness of laying up treasures on earth, by setting them apart for any distant, future, and uncertain use. They allow of public and private diversions, so far as they are not connected with circumstances really sinful; but apprehending a lot to be sacred, disapprove of playing at cards, dice, &c. They maintain a plurality of elders, pastors, or bishops, in each church; and the necessity of the presence of two elders in every act of discipline, and at the administration of the Lord's Supper. In the choice of these el-

ders, want of learning, and engagements in trade, &c. are no sufficient objection; but second marriages disqualify for the office; and they are ordained by prayer and fasting, imposition of hands, and giving the right hand of fellowship. In their discipline they are strict and severe; and think themselves obliged to separate from the communion and worship of all such religious societies as appear to them not to profess the simple truth for their only ground of hope, and who do not walk in obedience to it. We shall only add, that in every church transaction, they esteem unanimity to be absolutely necessary. From this abstract of the account which they have published of their tenets and practices, it does not seem to be probable that their number should be very considerable.

SAPOTA, in botany. See *ACHRA* in this APPENDIX.

SARPLAR of WOOL, a quantity of wool, otherwise called a *pocket*, or *half-jack*; a sack containing 80 tod; a tod two stone; and a stone 14 pounds.—In Scotland it is called *farpliath*, and contains 80 stone.

SASSAFRAS, a species of LAURUS; see LAURUS, (*Encycl.*). In Pennsylvania and other parts of North America, it grows in a dry loose ground, of a pale brick colour, which consists for the most part of sand mixed with clay. This tree spreads its roots very much, and new shoots come up from them in some places; but these shoots are not good for transplanting, because they have so few fibres besides the root which connects them to the main stem, that they cannot well strike into the ground. If, therefore, any one would plant sassafras trees, he must endeavour to get their berries; which, however, is difficult, since the birds eat them before they are half ripe. The cows are very greedy after the tender new shoots, and look for them every where.

The bark of this tree is used by the women here in dying worsted a fine lasting orange-colour, which does not fade in the sun. They use urine instead of alum in dying; and boil the dye in a brass boiler, because in an iron vessel it does not yield so fine a colour.

The wood is made use of for posts belonging to the enclosures, for it is said to last a long time in the ground: but it is likewise said, that there is hardly any kind of wood which is more attacked by worms than this, when it is exposed to the air without cover; and that in a short time it is quite worm-eaten through and through. On cutting some part of the sassafras tree, or its shoots, and holding it to the nose, it has a strong but pleasant smell. Some people peel the root, and boil the peel with the beer which they are brewing, because they believe it wholesome. For the same reason, the peel is put into brandy, either whilst it is distilling, or after it is made. Professor Kalm informs us, that a decoction of the root of sassafras in water, drank every morning, is used with success in the dropsy.

When part of a wood is destined for cultivation, the sassafras trees are commonly left upon it, because they have a very thick foliage, and afford a cool shade to the cattle during the great heats. Some people get their bed-posts made of sassafras wood, in order to expel the bugs; for its strong scent, it is said, prevents those vermin

from

Kalm's
Travels in
America.

from settling in them. For two or three years together this has the desired effect; or about as long as the wood keeps its strong aromatic smell; but after that time it has been observed to lose its effect. In Pennsylvania some people put chips of sassafras into their chells, where they keep all sorts of woollen stuffs, in order to expel the moths (or larvae or caterpillars of moths or tinies) which commonly settle in them in summer. The root keeps its smell for a long while: our author saw one which had lain five or six years in the drawer of a table, and still preserved the strength of its scent. The people here also gather its flowers, and use it as tea.

The sassafras-tree generally stands single in the woods, and along the fences round the fields. It flowers in May before the leaves come out; and being entirely covered with them, it is distinguished at a great distance by their beautiful yellow colour.

SCALDS, in the history of literature, a name given by the ancient inhabitants of the northern countries to their poets; in whose writings their history is recorded.

SCARBOROUGH, (*Encycl.*) The waters of Scarborough are chalybeate and purging. Of these there are two wells, both impregnated with the same principles, in different proportions; though the purging well is the most celebrated, and the water of this is usually called the *Scarborough water*. When these waters are poured out of one glass into another, they throw up a number of air-bubbles; and if they are shook for some time in a phial close stopped, and the phial be suddenly opened before the commotion ceases, they disengage an elastic vapour, with an audible noise, which flows that they abound in fixed air. At the fountain they have a brisk, pungent, chalybeate taste; but the purging water tastes bitterish, which is not usually the case with the chalybeate one. They lose their chalybeate virtues by exposure and by keeping; but the purging water the soonest. They both putrefy by keeping; but in time recover their sweetness. Four or five half pints of the purging water drank within an hour, give two or three easy motions, and raise the spirits. The like quantity of the chalybeate purges less, but exhilarates more, and passes off chiefly by urine. These waters have been found beneficial in hectic fevers, weaknesses of the stomach, and indigestion; in relaxations of the system; in nervous, hysterical, and hypochondriacal disorders; in the green sickness, scurvy, rheumatism, and asthmatic complaints; in gleets, the fluor albus, and other preternatural evacuations; and in habitual costiveness.

SCHOONER, in sea-language, a small vessel with two masts, whose main-sail and fore-sail are suspended from gaffs, reaching from the mast towards the stern, and stretched out below by booms, whose fore-most ends are hooked to an iron, which clasps the mast, so as to turn therein as upon an axis, when the after-ends are swung from one side of the vessel to the other.

SENSE, MORAL, is a determination of the mind to be pleased with the contemplation of those affections, actions, or characters, of rational agents, which we call good or virtuous.

This moral sense of beauty in actions and affections, may appear strange at first view: some of our moralists themselves are offended at it in lord Shaftes-

bury, as being accustomed to deduce every approbation, or aversion, from rational views of interest. Our gentlemen of good taste can tell us of a great many senses, tastes, and relishes, for beauty, harmony, imitation in painting and poetry; and may we not find too, in mankind, a relish for a beauty in characters, in manners? The truth is, human nature does not seem to have been left quite indifferent in the affair of virtue, to form to itself observations concerning the advantage or disadvantage of actions, and accordingly to regulate its conduct. The weakness of our reason, and the avocations arising from the infirmities and necessities of our nature, are so great, that very few of mankind could have framed those long deductions of reason, which may show some actions to be, in the whole, advantageous, and their contraries pernicious. The Author of Nature has much better furnished us for a virtuous conduct than our moralists seem to imagine, by almost as quick and powerful instructions as we have for the preservation of our bodies: he has made virtue a lovely form, to excite our pursuit of it; and has given us strong affections, to be the springs of each virtuous action. See *MORAL Philosophy*, (*Encycl.*)

SENSE, Public, is defined to be our determination to be pleased with the happiness of others, and to be uneasy at their misery. This, he says, is found in some degree in all men, and was sometimes called *κοινωνικητις*, or *sensus communis*, by some of the ancients.

SENSE, Common, is a term that has been variously used both by ancient and modern writers. With others it has been synonymous with public sense; with others it has denoted prudence: in certain instances, it has been confounded with some of the powers of taste; and, accordingly, those who commit egregious blunders with regard to decorum, saying and doing what is offensive to their company, and inconsistent with their own character, have been charged with a defect in common sense. Some men are distinguished by an uncommon acuteness in discovering the characters of others; and this talent has been sometimes called *common sense*: similar to which is that use of the term, which makes it to signify that experience and knowledge of life which is acquired by living in society. To this meaning Quintilian refers, speaking of the advantages of a public education: *Sensum ipsum qui communis dicitur, ubi discit. cum se a congressu, qui non hominibus solum, sed multis quoque animalibus naturalis est, segregavit?* Lib. i. cap. 2.

But the term *common sense* hath in modern times been used to signify that power of the mind which perceives truth, or commands belief, not by progressive argumentation, but by an instantaneous, inflexible, and irresistible impulse; derived neither from education nor from habit, but from nature; acting independently of our will, whenever its object is presented, according to an established law, and therefore called *sense*; and acting in a similar manner upon all, or at least upon a great majority of mankind, and therefore called *common sense*. The first among the moderns, who took notice of this principle as one of the springs of our knowledge, was Buffier, a French philosopher of the present century, in a book entitled *Traité des premières verités*; and this doctrine hath lately, in

our own country, been illustrated and maintained by Drs Reid, Beattie, Oswald, and Campbell.

In order to evince, that there is a real and essential difference between this faculty and that of reason, it is observed, that we are conscious, from internal feeling, that the energy of understanding, which perceives intuitive truth, is different from that other energy which unites a conclusion with a first principle, by a gradual chain of intermediate relations: that we cannot discern any necessary connection between reason and common sense: that the one is more in our power than the other; the faculty of reasoning being improvable by culture; whereas common sense, like other instincts, arrives at maturity with almost no care of ours, and it is impossible to teach common sense to one who wants it; though this, like other instincts, may languish for want of exercise: and that a distinction, similar to that which is here maintained, is acknowledged by the vulgar, who speak of mother-wit, as something different from the deductions of reason, and the refinements of science. All sound reasoning, it is said, must ultimately rest on the principles of common sense; that is, on principles intuitively certain, or intuitively probable; and, consequently, common sense is the ultimate judge of truth, to which reason must continually act in subordination. Thus the advocates for this faculty, as an original and distinct power of the human mind, assign to it a very extensive empire, and an authority that is supreme and absolute. And they have proceeded so far, as to substitute in the room of Mr Locke's *abstraction*, this faculty, as the characteristic of rationality. To this they refer the evidence of mathematical truth, of external and internal sense, of memory, of reasoning from the effect to the cause, of probable or experimental reasoning, of analogical reasoning, of faith in testimony, and, indeed, of all primary truths. To common sense, therefore, all truth must be conformable; this, they say, is its fixed and invariable standard. And whatever contradicts common sense, or is inconsistent with that standard, though supported by arguments that are deemed unanswerable, and by names that are celebrated by all the critics, academies, and potentates on earth, is not truth, but falsehood. In a word, the dictates of common sense are, in respect to human knowledge, in general, what the axioms of geometry are in respect to mathematics: on the supposition that these axioms are false or dubious, all mathematical reasoning falls to the ground; and on the supposition that the dictates of common sense are erroneous or deceitful, all truth, virtue, and science, are vain. And hence it appears, that according to this system, common sense is not only the test of truth, but the standard of moral obligation. See Reid's Enquiry into the Human Mind, on the Principles of *Common Sense*, 8vo, ed. 2. 1765. Beattie's Essay on the Nature and Immutability of Truth, 8vo, ed. 2. 1771. Oswald's Appeal to *Common Sense* in behalf of Religion, 8vo, ed. 2. 1768. Campbell's Philosophy of Rhetoric, 8vo, 1776, vol. i. p. 109, &c.

This system has been attacked by Dr Priestley; who has again been replied to (by Dr Blacklock, if we are not misinformed) in a late periodical publication at Edinburgh. See Priestley's Examination of Reid,

Beattie, and Oswald; also Edinburgh Magazin and Review for the year 1775.

SERPENTS, (*Encycl.*) Serpents strike mankind, and other animals, with such terror upon account of their poison and some singular properties which elude all the distinction of our judgment, that their unexpected approach alarms even the most determined courage. Among the amphibia serpentes we find some genera endued with a very singular quality, whereby they differ from all others: the greater part of them live indifferently by land or water, many of them for one half the year sleep in their winter-quarters to all appearance dead: their respiration differs very much from that of birds and the Mammalia; they draw in air without any reciprocal expiration, at least a sensible one: their bodies are of a very rigid nature, abounding with blood, which possesses a very small degree of heat: the organs of generation in the male are double; a singularity occurring in no other animal, unless perhaps a few insects: their natural sounds are hoarse, their aspects ugly, their smell fetid. Some of them are oviparous, others viviparous; and by their having cartilaginous bones, every spring they shake off their old age in the manner of the crab; so that there is no definitive bound to their increase and magnitude. Their singular mode of taking their prey also deserves to be mentioned: being destitute of feet, and consequently not able to pursue it, they lie hidden under the cover of large stones and the roots of trees, and darting forward with a sudden spring upon any animal which passes by, seize and devour it. Travellers into India inform us, that the *Boa constrictor*, the greatest of all serpents, lies in ambush among shrubs, and seizing hares, stags, and other animals, suffocates them by rolling himself round them, and then covering them with his saliva, swallows them. These animals, as they very seldom happen of capture, and beside are not furnished with real and proper grinding teeth, have not their jaw-bones jointed with the same articulation as other animals, but only connected at the base with a ligament; so that by expanding them they are able to devour the body of an animal of twice their thickness, or even more: Thus Cleijer relates, that the *boa* of Java will devour a whole buffalo, and other travellers affirm that he is able to swallow a stag. Our own vipers are frequently seen with their bellies greatly swelled out; and being dissected, they will be found to contain a frog or a mouse. A writer in the *Amenitates Academicæ*, informs us, that he once discovered seven young birds in the stomach of a viper.

The American rattlesnake is the most indolent of all the serpents: As he lies under the shade of a tree, opening his jaws a little, he fixes his eyes, which glitter very brightly upon any bird or squirrel which is in it: they are endued with a wonderful power of fascination; the squirrel utters a mournful and feeble cry, and, as if foreseeing his fate, leaps from bough to bough on every side, seemingly to attempt a sudden escape; but struck with an unknown species of fascination, he comes down from the tree, and flings himself with a spring into the very jaws of his enemy. A mouse, having been shut up with one of these fascinating rattlesnakes in an iron box, the mouse sat in one corner, and the rattlesnake was opposite to it; and fixing

his

his eyes continually upon it, by his look alone it was at last forced to fling itself into the mouth of the serpent. The same experiment was repeated in Italy with a pregnant female viper with the same success; and do we not see in the summer a parallel instance at home in the toad, a most indolent animal, into whose mouth, as it lies in the shade or under a shrub, butterflies and other insects fly?

Weapons. No subject has excited more philosophical controversy than the poison of serpents, with regard to its nature and mode of operating. Antiquity has not been sparing in conjecture and fiction upon this subject, and its errors have been retained with the most reverential obsequy by the vulgar: among these we are to reckon the fictitious sting fixed in the tail of the serpent, as the painters sometimes have groundlessly enough represented it; some have invented a similar fiction of a black forked tongue, which the serpent vibrates on both sides, and have ascribed its power of producing such noxious effect to this; while others, affixing an air of superior discernment, have, upon equally good reasons, ascribed it to the teeth in general: these are all errors of a magnitude that the most desultory attention to the subject would have been sufficient to have removed. There is a very small bone closely fixed to the upper jaw, in the inside of the lip of a poisonous serpent, which has a power of moving backward or forward; to this two or three fangs are annexed larger than the teeth, which the serpent, by its assistance, when enraged, darts forward, or withdraws and conceals at his pleasure, in a similar manner to the claws of a cat: these fangs, which the common people name the large teeth of the serpent, are excellently described by Tyson, in the anatomy of the rattlesnake, which he has given in the Philosophical Transactions. "In these (the fangs) we observed a considerable cavity near the base; and near the point a very discernible fissure of some length like the slit of a pen: the part of the tooth from the fissure to the root was manifestly channelled, which we first discovered by lightly pressing the gums; we then saw the poison ascend through the cavity of the fang and flow out of the fissure; and as these fangs are so very acute, so firm and solid toward the point (the fissure being on the external and convex, not the internal side), nothing could be conceived more convenient either for inflicting a wound, or to insure the infusion of the poison." Each of the fangs is surrounded with a vesicle furnished with glands secreting a certain fluid; which, upon the vesicle being pressed, seems to flow out of the point of the fang. The serpent when incensed, raising his head, extends the small bone armed with the fangs mentioned above; and attacking his enemy with a force combined of the weight of his body and the action of the muscles, he wounds him with the expanded fangs, and the vesicle being compressed the poison immediately flows into the wound: this is clear from the experience of those who, having broken off their fangs with a pair of forceps, handled the serpent thus disarmed without any hurt. And as the North Americans, after carefully extracting these venomous fangs, suffer the rattlesnake to bite and gnaw them with his teeth till the blood flows freely, with total impunity; it is certain those people are deceived who attribute the fatal effects of his bite to those hurtless weapons.

Poison. Antiquity amused itself with a fable destitute of all appearance of truth, that anger was excited by black bile: they applied this fiction without hesitation to the present subject, and founded an hypothesis upon it to account for the effects of the bite of an incensed serpent; pretending to have discovered an ideal canal which conducted the bile from its vesicle to the mouth of the serpent, whence it flowed into the part bitten, and produced the most fatal symptoms. But toward the end of the last century, this subject was greatly illustrated under the auspices of Ferdinand the Second, Great Duke of Tuscany: This prince, desirous of inquiring into that mysterious question, the nature of serpents, invited Srenio, Rhedi, and some other philosophers of the first eminence, to his court; and a multitude of the most poisonous serpents being collected, Rhedi made several experiments upon them, which discovered to him a number of particulars before unknown; of which the following seem to have the best claim to our attention. When he either caused a living viper to bite a dog, or wounded him with the teeth of one newly dead (the poisonous vesicle remaining unbroken), the event was the same. If the bite was repeated, its effect became weaker, and at last was lost, the poison contained in the vesicle being totally exhausted. That the teeth of serpents, when extended to bite, were moistened over with a certain liquor; and when the vesicle at the base was pressed, a drop of poison flowed to the point of the fang. When the poison thus flowing from the vesicle was received in soft bread or a sponge, an animal bitten by the serpent received no more harm from the wound than from being pricked by a needle, till after a few days, when the venom was restored afresh: but when an animal was wounded with the point of a needle dipped in the poison, it was tormented with the same pains as if it had been bitten by the viper itself. Preserving some of this poison in a glass, and totally evaporating the moisture in the sun, when the residuum was diluted again with water, and the point of a needle dipped in the solution, Rhedi found to his great surprise that it had the same effect as when recent. But the boldness of Tozzi, one who charmed vipers, slung all these men who were deeply versed in natural philosophy into the utmost astonishment; they happening to fall into discourse (while the prince was present) upon the certain death which would attend any person's swallowing this poison of the viper by mistake, instead of spirit of wine or water; Tozzi, confiding in his art, drank a considerable portion of it without hesitation: they were all astonished at his apparent rashness, and predicted instant death to the man; however, he escaped as safely as if he had drunk only so much water. This event, which struck the prince and his illustrious associates in these philosophical inquiries by its novelty, was well known to the ancients. Lucan, in the 9th book of the Pharsalia, speaking of the serpent, says,

*Nosia serpentum est admisso sanguine pessis
Morsu virus habent, et salum dente minantur.
Pocula morte carent.* Phar. l. 9, v. 614.

Mixed with the blood that venom slays alone,
His bite is poison, death is in his fang;
Yet is the draught innoxious.

Nor must we omit observing, that barbarous nations are perfectly acquainted with the property of the poi-

fon of serpents by which it retains its deadly power after it has been long kept : they have been possessed of this fatal secret for ages past ; it being their custom to tinge the points of their arrows with the juice of spurge, putrid flesh, or oil of tobacco, but more particularly with the poison of vipers. Some modern Indians continue the practice to this day ; and we have the testimony of Pliny, in his Natural History, that the Scythians had long ago the same custom : " The Scythians (says that author) dip their arrows in the poison of vipers and human blood ; a horrid practice, as the slightest wound inflicted by one of them defies all the art of medicine."

While Rhedi and his associates were thus busied in Tuscany in tracing the footsteps of nature closely and successfully under the guidance of experiment, the philosophers of other countries amused themselves with forming new conjectures and fictions. In France, Moses Charas, first surgeon to the king, a man of considerable reputation, writing upon the theory of serpents, endeavoured with all his weight to prove their poison " to consist in heated animal-spirits, and therefore that it is impossible for a viper to give a deadly wound unless it had been before incensed." We shall not go about to deny, that the mental affections can generate something similar to a poison. The face of a man in anger, changed to a sublivid colour, indicates something like it : men struck with a sudden terror frequently turn pale, and the humours lodged in the intestinal canal are evacuated by a diarrhœa. But this is evidently discovered in nurses, whose milk becomes poisonous when they are greatly irritated ; and if it be then taken by a child, provokes a diarrhœa, which frequently terminates fatally. But however this may be, the hypothesis of Charas can receive but little support from it ; as that vague doctrine of animal spirits and their irritation, however it might afford a commodious and decent retreat to ignorance formerly, is now suffered to subside in a very undisturbed oblivion.

Bite. The symptoms that attend the bite of the viper are a smarting in the part wounded, as if it were continually pricked with needles ; swelling, paleness, snapping of the eyes, tears, horror with coldness ; a weak pulse, afterwards becoming unequal ; thirst, cold sweat, pain in the reins, diarrhœa with griping and vomiting, difficulty of breathing, drowsiness, and convulsions which terminate in death.

We are ignorant of what species the hemorrhoids was, which is described by Lucan as causing by its bite a flux of blood from every part of the body. But the bite of an American serpent named *de la cruz* kills in the same manner.

The diphasia is at present likewise unknown. Lucan informs us, that the person wounded by it was attacked by an unquenchable thirst. This is finely painted by him ; where A. Tuscus, standard-bearer of Cato, is described as bitten by that serpent :

*Non decus imperii, non missi jura Catonis
Ardentem tenere virum, quin spargere signa
Auderet, totisque furens exquireret agris
Quas poscebat aquas sitiens in corde venenum.*

Phaësa. l. 9.

His wild impatience, not his honoured state,
Nor forrowing Cato's high command, restrain ;
Furious, dishonoured in the dust, he flings

His sacred eagle, and o'er all the fields
Rapid he bursts to seek the cooling stream,
To quench the thirsty poison in his breast.

And a few verses after :

*Scrutatur venas penitus squalentis arena
Nunc redit ad Syrtis, et fluctus accipit ore,
Aqueoræque placet, sed non sibi sufficit humor,
Nec sentit satique genus, martemque veneni,
Sed putat esse sitim ; ferroque aperire tumentes
Sustulnit venas, atque os implere cruore.*

Now tearing up the sands, some latent vein
Frustrate he seeks ; now to the Syrtis shore
Return'd, he swallows down the briny flood
Mixed with its rolling sands ; nor knows his fate
And the sad poison's death, but calls it thirst ;
Then with his sword opens his spouting veins,
And drinks the bursting blood.—

In the monuments of antiquity we find three species of asps.

1. The phytas, with a callous caruncle on its forehead : its colour is cinereous, with a shining green.

2. The chersea, is very long, cinereous, inclining to green ; its eyes red.

3. The chelidonia is black, with a white belly : its bite is said to produce two or three hiccoughs, change of colour, stupor, cold, and sleep with palpitation. Upon a comparison of what these authors have written upon these asps, it seems probable that the phytas, which kills by bringing on a lethargic sleepiness, is the same serpent which obtained the specific name of the *aspis* among the ancients, and that it is the nintipolonga Zeylanica of Bellonius and Ray, and the Amodytes of Linnæus. The phytas seems to have been the serpent made use of by Cleopatra to destroy herself. This woman, to terminate a dissipated life with an easy death, ordered her physicians to prepare a poison for her which might best effect this purpose. They having tried a number of different experiments upon condemned criminals, at last discovered this species of asp, which brings on death without any previous appearance of distemper or hiccough : the face seems in a slight perspiration, an easy insensibility and lethargy creeps upon the whole frame, and the person bitten seems almost totally ignorant of his approaching dissolution. Having acquainted the queen with their discovery, he applied the asp either to her bosom or her arms ; or, according to some authors, dipping the point of a needle in the poison, and pricking herself with it, she expired in an easy sleep. Most of the **COLORATI** are poisonous, and perhaps all the **CROTALI** : among these are reckoned

| | |
|------------|--------------------------|
| Vipera, | Myæterizans, |
| Berus, | Leberia, |
| Lebetinus, | Prestor, or black viper, |
| Naja, | Stolatus, |
| Diphas, | Niveus, |
| Atropos, | Amodytes, |
| Chersea, | Apis, |
| Severus, | Laëdus, |
| Atrox, | Corallinus. |

The bite of the naja is so fatal, that a man dies by it in the space of an hour, his flesh entirely falling off his bones in a semi-dissolved putrid state : this makes it probable that it is the same serpent which the ancients named the *sepe*. It is not necessary to enume-

rate

rate any more, though a number of different species might be mentioned whose poisons all produced different effects: yet with this diversity, according to Rhedi, they all agree in one particular circumstance, that their venom is not fatal unless introduced into the blood externally.

The experiments of Rhedi have not, however, in the opinion of some celebrated philosophers, so far cleared the theory of the operation of the poison of the viper, as to leave nothing further to be desired upon that subject. Fontana and Carminati have endeavoured to investigate its operations more clearly. Carminati, from eleven experiments, deduces the following conclusions. 1. That if poison be infused into a nerve, the animal wounded dies almost instantly; and the whole nervous system, to which it is rapidly conveyed, is deprived of its quality called *sensibility*. 2. If a muscle be wounded, it is deprived of its irritability. This is confirmed by the experiments of Fontana. 3. The poison injected into a wounded muscle or tendon is considerably longer in killing an animal than that introduced into a nerve. 4. The symptoms which precede the death of the animal bitten are, a stupor, lethargy, tremors, convulsions, paralysis of the legs (part wounded), entire dissolution of the limbs. The blood is not always coagulated, nor its crasis dissolved. Marks of inflammation are sometimes discovered in certain parts of the animal after death, sometimes not: these are the effects of spasms and convulsions, not of the poison. 5. Not the least sign of the jaundice was discoverable in the eyes of any of the animals upon which Carminati made his experiments. 6. The stomach in every one of them was very much inflated; a symptom remarked only by Fallopius and Albertini. 7. A ligature applied instantly above the part bitten, if it be so placed as to admit one, was found by some experiments a good preventative against the diffusion of the poison: its compression should be considerable, but not excessive.

Cure. It would be endless to attempt to relate all those antidotes which men, compelled by so fatal a necessity, have employed against the bite of serpents. We shall confine ourselves only to such as are recommended by the probability of use. The first in point of antiquity, and which recommends itself also to us by its certainty, is to draw the venom out of the wounded part as quickly as possible. This has been attempted by different methods. The most ancient is sucking it out by the mouth: yet the utmost precaution is necessary in the person who performs this operation, that his mouth be perfectly free from the scurvy, and that the skin of the fauces be entirely unbroken; lest he should incur an equal hazard, or perhaps a greater, as the poison must attack a nobler part. Therefore, as the operation is nauseous and full of danger, it will be better to scarify the part with the knife, that the infected blood may have a freer exit from the opened mouths of the vessels, and to apply a large cupping-glass, by means of which the remaining venom may be extracted; then to foment the part with warm emollient applications, joined with some spirit, as the spirit of sal ammoniac or theriacum; if these be not at hand, apply soap and vinegar to the wound: the patient may take sudorific and exciting medicines internally, by which is meant emetics or ipecacuanha; and

the stronger sudorifics are exhibited with great success. But the present age has added antidotes of three different species to counteract the most vehement effects of this poison, of which *Europe, America, and Asia*, has each furnished us with one.

1. Among the *Europeans*, there has been a strong predilection in favour of the oil of olives, or any other expressed oil: this is directed to be drunk plentifully by the patient, to the quantity of half a pound or more, while the wounded part is copiously bathed by it. Very full accounts of the happy effects of this treatment are inserted in the Philosophical Transactions of London, and the Memoirs of the Academy of Paris. We are so far from detracting from the merits of this medicine, that we think it specific against the bite of the common and black viper; yet we must add, that the nature of this antidote is not yet thoroughly investigated and understood, and that we dare not pronounce sentence upon its efficacy and use in every single and particular case. Linnæus, being in Scania, was applied to by a woman who was bitten by the chersia; and notwithstanding he caused her to drink this oil according to the prescribed forms, she nevertheless expired in the greatest agonies. May not this oil fail when applied against the bite of some of the European species of serpents? or is there not some necessary observations omitted in the formula delivered, either respecting the medicine or the patient? This we leave and strongly recommend to the experience of others to determine.

2. Let us now proceed to the *American* antidotes; of which the powder of the senega root deservedly claims the first place. The use of this root has been known to the natives of the woods of North America for many ages past. Its effects against the bite of the rattlesnake almost exceed all belief; but the invidious prejudices of those barbarians preserved this secret with so obstinate a silence, that no bribe could purchase it from them, until Tennent happily discovered and published it for the benefit of mankind. He tells us, that the root of the polygala senega never fails of success unless, where some large vessel is wounded, when the medicine has not time to counteract the rapid progress of the violence of the poison. Upon this subject the reader may consult the Dissertation upon this plant in the second volume of the *Amœnitates Academicæ*. A maid-servant at Upsal was bitten by a serpent upon a very dangerous place. The most dreadful symptoms followed the bite, and such as demanded the application of the most decisive remedies. Two doses of the powder of this root was attended with so good an effect, that in two days she was almost completely recovered. Beside this root, the Americans have many other plants which they apply upon the same occasion; as the eryngium foetidum, or American fetid eryngo; aquaticum, or Virginian aquatic ditto; veratrum luteum, or Virginian yellow-flowered veratrum; alctris farinosa, or floridan alctris; uvularia perfoliata, or Virginian perfoliate uvula; fanicula canadensis, or Canadian fanicle; and the aristolochia serpentaria, or Virginian snake-root: but we shall dismiss these, with a long catalogue of others whose virtues are not yet well known to us.

3. We come now to another antidote of equal celebrity, that made use of by the *Asiatics*, which is of

the greatest antiquity among the Indians, the ophiorrhiza mungos, or Indian ophiorrhiza. Kæmpfer has given us the history of this plant and its unequalled virtues against the bite of the coluber najas, or cobra di capello. We shall only hint, that as the efficacy of this medicine is so great, it would be much safer to introduce that, or the true lignum colubrinum, instead of the strychnos colubrina, or Indian strychnos, into general practice, whose use, if it have any, is extremely ambiguous.

The snake-stone, called the *pedra de cobras di capello* (as if it were a stone extracted from the head of the coluber naja) is very famous throughout all India, and is extolled by Garzia, Kircher, and others, as a specific against the bite of serpents. It is pretended, that if it be applied to a poisoned wound, and suffered to remain upon it until it fall off of itself, that it will extract all the venom. But its use has been suspected by many; nor did it succeed with Rhedi, who tried a variety of experiments with it. Many have been of opinion that the stone is artificial, and nothing more than the calcined horn of a hart. See PSYLLI, (*Encycl.*)

SHAKE, (*Encycl.*) See TRILL, below.

SHELLS, POLISHING OF. This is an art of no long standing in the world in its present perfection; and as the love of sea-shells is become so common among us, it may not be disagreeable to the reader to find some instructions in executing so pleasing a method of adding to their natural beauty, the rules for which are at present so little known, though the effect of them be so much esteemed.

Among the immense variety of shells which we are acquainted with, some are taken up out of the sea, or found on its shores in all their perfection and beauty; their colours being all spread by nature upon the surface, and their natural polish superior to any thing that art could give. Where nature is in herself thus perfect, it were madness to attempt to add any thing to her charms: but in others, where the beauties are latent and covered with a coarser outer skin, art is to be called in; and the outer veil being taken off, all the internal beauties appear.

Among the shells which are found naturally polished are, the porcelains, or cowries; the caissons; the dolia, or conchæ globosæ, or tuns; some buccina, the volute, and the cylinders, or olives, or, as they are generally though improperly called, the *rhombi*; excepting only two or three, as the tiara, the plumb, and the butter-tub rhombus, where there is an unpromising film on the surface, hiding a very great share of beauty within. Though the generality of the shells of these genera are taken out of the sea in all their beauty, and in their utmost natural polish, there are several other genera, in which all or most of the species are taken up naturally rough and foul, and covered with an epidermis, or coarse outer skin, which is in many rough and downy or hairy. The tellinæ, the muscels, the cochleæ, and many others, are of this kind. The more nice collectors, as naturalists, insist upon having all their shells in their native and genuine appearance, as they are found when living at sea; but the ladies, who make collections, hate the disagreeable outdoes, and will have all such polished. It would be very advisable, however, for both kinds of

collectors to have the same shells in different specimens, both rough and polished: the naturalist would by this means, besides knowing the outside of the shell, be better acquainted with its internal characters than he otherwise could be, and the lady would have a pleasure in comparing the beauties of the shell, in its wrought state, to its coarse appearance as nature gives it. How many elegancies in this part of the creation must be wholly lost to us, if it were not for the assistance of an art of this kind! Many shells in their native state are like rough diamonds, and we can form no just idea of their beauties till they have been polished and wrought into form.

Though the art of polishing shells is a very valuable one, yet it is very dangerous to the shells; for without the utmost care, the means used to polish and beautify a shell often wholly destroy it. When a shell is to be polished, the first thing to be examined is whether it have naturally a smooth surface, or be covered with tubercles or prominences.

A shell which has a smooth surface, and a natural dull polish, need only be rubbed with the hand, or with a piece of chamoy leather, with some tripoli, or fine rotten stone, and will become of a perfectly bright and fine polish. Emery is not to be used on this occasion, because it wears away too much of the shell. This operation requires the hand of an experienced person, that knows how superficial the work must be, and where he is to stop; for in many of these shells the lines are only on the surface, and the wearing away ever so little of the shell defaces them. A shell that is rough, foul, and crusty, or covered with a tartareous coat, must be left a whole day sleeping in hot water: when it has imbibed a large quantity of this, it is to be rubbed with rough emery on a stick, or with the blade of a knife, in order to get off the coat. After this, it may be dipped in diluted aquafortis, spirit of salt, or any other acid; and after remaining a few moments in it, be again plunged into common water. This will add greatly to the speed of the work. After this it is to be well rubbed with linen cloths, impregnated with common soap; and when by these several means it is made perfectly clean, the polishing is to be finished with fine emery and a hair-brush. If after this the shell when dry appears not to have so good a polish as was desired, it must be rubbed over with a solution of gum arabic; and this will add greatly to its gloss, without doing it any sort of injury. The gum-water must not be too thick, and then it gives no sensible coat, only heightening the colours. The white of an egg answers this purpose also very well; but it is subject to turn yellow. If the shell has an epidermis, which will by no means admit the polishing of it, it is to be dipped several times in diluted aquafortis, that this may be eaten off; and then the shell is to be polished in the usual way with putty, fine emery, or tripoli, on the hair of a fine brush. When it is only a pellicle that hides the colours, the shells must be steeped in hot water, and after that the skin worked off by degrees with an old file. This is the case with several of the cylinders, which have not the natural polish of the rest.

When a shell is covered with a thick and fatty epidermis, as is the case with several of the muscels and tellinæ; in this case aquafortis will do no service, as it

it will not touch the skin: then a rough brush and coarse emery are to be used; and if this does not succeed, pumice-stone, or, as the workmen call it, *fijf-skin* and *pumice-stone*, are to be employed.

When a shell has a thick crust, which will not give way to any of these means, the only way left is to plunge it several times into strong aquafortis, till the stubborn crust is wholly eroded. The limpets, *auris marina*, the helmet-shells, and several other species of this kind, must have this sort of management; but as the design is to show the hidden beauties under the crust, and not to destroy the natural beauty and polish of the inside of the shell, the method of using the aquafortis must be this: A long piece of wax must be provided, and one end of it made perfectly to cover the whole mouth of the shell; the other end will then serve as a handle, and the mouth being stopped by the wax, the liquor cannot get in to the inside to spoil it; then there must be placed on a table a vessel full of aquafortis, and another full of common water.

The shell is to be plunged into the aquafortis; and after remaining a few minutes in it, is to be taken out, and plunged into the common water. The progress the aquafortis makes in eroding the surface is thus to be carefully observed every time it is taken out: the point of the shell, and any other tender parts, are to be covered with wax, to prevent the aquafortis from eating them away; and if there be any worm-holes, they also must be stopped up with wax, otherwise the aquafortis would soon eat through in those places. When the repeated dippings into the aquafortis show that the coat is sufficiently eaten away, then the shell is to be wrought carefully with fine emery and a brush; and when it is polished as high as can be by this means, it must be wiped clean, and rubbed over with gum-water or the white of an egg. In this sort of work the operator must always have the caution to wear gloves; otherwise the least touch of the aquafortis will burn the fingers, and turn them yellow; and often, if it be not regarded, will eat off the skin and the nails.

These are the methods to be used with shells which require but a moderate quantity of the surface to be taken off; but there are others which require to have a larger quantity taken off, and to be uncovered deeper: this is called entirely scaling a shell. This is done by means of an horizontal wheel of lead or tin, impregnated with rough emery; and the shell is wrought down in the same manner in which stones are wrought by the lapidary. Nothing is more difficult, however, than the performing this work with nicety: very often shells are cut down too far by it, and wholly spoiled; and to avoid this, a coarse vein must be often left standing in some place, and taken down afterwards with the file, when the cutting it down at the wheel would have spoiled the adjacent parts.

After the shell is thus cut down to a proper degree, it is to be polished with fine emery, tripoli, or rotten stone, with a wooden wheel turned by the same machine as the leaden one, or by the common method of working with the hand with the same ingredients. When a shell is full of tubercles, or protuberances, which must be preserved, it is then impossible to use the wheel; and if the common way of dipping into aquafortis be attempted, the tubercles being harder than

the rest of the shell, will be eat through before the rest is sufficiently scaled, and the shell will be spoiled: in this case industry and patience are the only means of effecting a polish. A camel's-hair pencil must be dipped in aquafortis; and with this the intermediate parts of the shell must be wetted, leaving the protuberances dry: this is to be often repeated; and after a few moments the shell is always to be plunged into water to stop the erosion of the acid, which would otherwise eat too deep, and destroy the beauty of the shell. When this has sufficiently taken off the foulness of the shell, it is to be polished with emery of the finest kind, or with tripoli, by means of a small stick, or the common polishing stone used by the goldsmiths may be used.

This is a very tedious and troublesome thing, especially when the echinated oysters and murexes, and some other such shells, are to be wrought: and what is worst of all is, that when all this labour has been employed, the business is not well done; for there still remains several places which could not be reached by any instrument, so that the shell must necessarily be rubbed over with gum-water or the white of an egg afterwards in order to bring out the colours and give a gloss; in some cases it is even necessary to give a coat of varnish.

These are the means used by artists to brighten the colours, and add to the beauty of shells; and the changes produced by polishing in this manner are so great, that the shell is often not to be known afterwards for the same it was; and hence we hear of new shells in the cabinets of collectors, which have no real existence as separate species, but are the polished appearance of others well known. To caution the reader against errors of this kind, it may be proper to add the most remarkable species thus usually altered.

The onyx-shell or volute, called by us the *purple* or *violet-tip*, which in its natural state is of a simple pale brown, when it is wrought slightly, or polished with just the superficies taken off, is of a fine bright yellow; and when it is eat away deeper, it appears of a fine milk-white, with the lower part bluish: it is in this state that it is called the *onyx-shell*; and it is preserved in many cabinets in its rough state, and in its yellow appearance, as different species of shells.

The violet shells, so common among the curious, is a species of porcelain, or common cowry, which does not appear in that elegance till it has been polished; and the common *auris marina* shows itself in two or three different forms, as it is more or less deeply wrought. In its rough state it is dusky and coarse, of a pale brown on the outside, and pearly within; when it is eaten down a little way below the surface, it shows variegations of black and green; and when still farther eroded, it appears of a fine pearly hue within and without.

The nautilus, when it is polished down, appears all over of a fine pearly colour; but when it is eaten away but to a small depth, it appears of a fine yellowish colour with dusky hairs. The burgau, when entirely cleared of its coat, is of the most beautiful pearl-colour: but when once slightly eroded, it appears of a variegated mixture of green and red; whence it has been called the *parroquet shell*. The common helmet-shell, when wrought, is of the colour of the finest a-

gate;

Shells.

gate; and the mufcles, in general, though very plain fhells in their common appearance, become very beautiful when polished, and fhew large veins of the moft elegant colours. The Perfian fhell, in its natural ftate, is all over white, and covered with tubercles; but when it has been ground down on a wheel, and polished, it appears of a grey colour, with fpoats and veins of a very bright and highly polished white. The limpets in general become very different when polished, moft of them fhewing very elegant colours; among thefe the tortoise-shell limpet is the principal; it does not appear at all of that colour or tranfparency till it has been wrought.

That elegant fpecies of fhell called the *junquilha*, which has deceived fo many judges of thefe things into an opinion of its being a new fpecies, is only a white chama with a reticulated furface; but when this is polished, it lofes at once its reticular work and its colour, and becomes perfectly fmooth, and of a fine bright yellow; and the violet-coloured chama of New England, when worked down and polished, is of a fine milk-white, with a great number of blue veins, difpofed like the variegations in agates.

The afles-ear fhell, when polished after working it down with the file, becomes extremely glosfy, and obtains a fine rofe-colour all about the mouth. Thefe are fome of the moft frequent among an endlefs variety of changes wrought on fhells by polishing; and we find there are many of the very greateft beauties of this part of the creation, which muft have been loft but for this method of fearching deep in the fubftance of the fhell for them.

The Dutch are very fond of fhells, and are very nice in their manner of working them: they are under no reftRAINT, however, in their works; but ufe the moft violent methods, fo as often to deftroy all the beauty of the fhell. They file them down on all fides, and often take them to the wheel, when it muft deftroy the very characters of the fpecies. Nor do they ftop at this; but, determined to have beauty at any rate, they are for improving upon nature, and frequently add fome lines and colours with a pencil, afterwards covering them with a fine coat of varnifh; fo that they feem the natural lineations of the fhell: the Dutch cabinets are by this means made very beautiful, but they are by no means to be regarded as inftructors in natural hiftory. There are fome artificers of this nation who have a way of covering fhells all over with a different tinge from that which nature gives them; and the curious are often deceived by thefe tricks: into the purfuing them as new fpecies.

There is another kind of work beftowed on certain fpecies of fhells, particularly the nautilus; namely, the engraving on it lines and circles, and figures of ftars, and other things: this is too obvious a work of art to fuffer any one to fuppofe it natural. Buonani has figured feveral of thefe wrought fhells at the end of his work; but it is miferably throwing away labour to do them; the fhells are fpoiled as objects of natural hiftory by it, and the engraving is feldom worth any thing. They are principally done in the Eaft Indies.

Shells are fubject to feveral imperfections; fome of which are natural, and others accidental. The natural ones are the effect of age, or ficknefs in the fift. The

greateft mischief happens to fhells by the fift dying in them. The curious in thefe things pretend to be always able to diftinguifh a fhell taken up with the fift alive, from one found on the fhores: they call the fift a *living*, the fecond a *dead* fhell; and fay that the colours are always much the fainteft in the dead fhells. When the fhells have lain long dead on the fhores, they are fubject to many injuries, of which the being eaten by fea worms is not the leaft: age renders the fineft fhells livid or dead in their colours.

The fineft fhells are thofe which are fifted up at fea, not found on the fhores. The other natural defects of fhells are their having morbid cavities, or protuberances, in parts where there fhould be none. When the fhell is valuable, thefe faults may be hid, and much added to the beauty of the fpecimen without at all injuring it as an object of natural hiftory, which fhould always be the great end of collecting thefe things. The cavities may be filled up with mafic, d folved in fpirit of wine, or with ifinglafs: thefe fubftances muft be either coloured to the tinge of the fhell, or elfe a pencil dipped in water-colours muft finifh them up to the refemblance of the reft; and then the whole fhell being rubbed over with gum-water, or with the white of an egg, fcarce any eye can perceive the artifice: the fame fubftances may alfo be ufed to repair the battered edge of a fhell, provided the pieces chipped off be not too large. And when the excrefcences of a fhell are faulty, they are to be taken down with a fine file. If the lip of a fhell be fo battered that it will not admit of repairing by any cement, the whole muft be filed down to an evennefs, or ground on the wheel.

SHERIDAN (Mrs Frances), wife to Thomas Sheridan, M. A. was born in Ireland about the year 1724, but defcended from a good Englifh family which had removed thither. Her maiden name was Chamberlaine, and fhe was grand-daughter of Sir Oliver Chamberlaine. The firft literary performance by which fhe diftinguifhed herfelf was a little pamphlet at the time of a violent party-difpute relative to the theatre, in which Mr Sheridan had newly embarked his fortune. So well-timed a work exciting the attention of Mr Sheridan, he by an accident difcovered his fair patronnefs, to whom he was foon afterwards married. She was a perfon of the moft amiable character in every relation of life, with the moft engaging manners. After lingering fome years in a very weak ftate of health, fhe died at Blois, in the fourth of France, in the year 1767. Her "Sydney Biddulph" may be ranked with the firft productions of that clafs in ours or in any other language. She alfo wrote a little romance in one volume, called *Nou-jahad*, in which there is a great deal of imagination productive of an admirable moral. And fhe was the authorefs of two comedies, "The Difcovery" and "The Dupe."

SIDUS, GEORGIVM, in aftronomy, a new primary planet, difcovered by William Herfchel, Efq; of Bath, in the year 1781, for which he obtained from the Royal Society the honorary recompence of Sir Godfrey Copley's medal; and fo called in honour of his majefty king George III. who has taken Mr Herfchel under his patronage, and granted to him an annual falary. "From many calculations of our beft

Sheridan,
Sidus.

astronomers and mathematicians, says Mr Herichel, I have collected the following particulars, as most to be depended upon.

| | | |
|--------------------------------|---|----------------------------------------|
| Place of the node | - | 2 ^s 11 ^d 49' 30" |
| Inclination of the orbit | - | 43' 35" |
| Place of the perihelion | - | 172 ^d 13' 17" |
| Time of the perihelion passage | - | Sep. 7, 1799 |
| Eccentricity of the orbit | - | .82034 |
| Half the greater axis | - | 19,97904 |
| Revolution | - | 83,3364 sidereal years. |

From my own observations on this planet's apparent diameter, which I have found cannot well be less than 4", nor indeed much greater, we infer that its real diameter is to that of the earth as 4,454 to 1; and hence it appears to be of very considerable bulk, and, except Saturn and Jupiter, by far the largest of the remaining planets. Its light is of a bluish-white colour, and in brilliancy between that of the Moon and of Venus. With a telescope which magnifies about 300 times, it appears to have a very well defined visible disk; but with instruments of a small power, it can hardly be distinguished from a fixed star of between the sixth and seventh magnitude. In a very fine clear night, when the moon is absent, it may also be seen by the naked eye."

SIGHING, an effort of nature, by which the lungs are put into greater motion, and more dilated, so that the blood passes more freely, and in greater quantity, to the left auricle, and thence to the ventricle. Hence we learn, says Dr Hales, how sighing increases the force of the blood, and consequently proportionably cheers and relieves nature, when oppressed by its too slow motion, which is the case of those who are dejected and sad.

SILK, SERICUM, a very soft, fine, bright, delicate thread; the work of an insect, called *bombyx* or the *silk-worm*. See **SILK**, (*Encycl.*)

The ancients were but little acquainted with the use and manufacture of silk; they took it for the work of a sort of spider, or beetle, who spun it out of its entrails, and wound it with its feet about the little branches of trees. This insect they called *ser*, from *Seres*, a people in Scythia, whom we now call the *Chinese*, who, as they thought, bred it; whence the silk itself they called *sericum*. But this *ser* of theirs has very little affinity with our silk-worm, *bombyx*; the former living five years; but the latter dying annually, enveloped in a yellowish bag, or ball, which, wound out into little threads, makes what we call *silk*.

It was in the isle of Cos that the art of manufacturing silk was first invented; and Pamphila, daughter of Platis, is honoured as the inventress. The discovery was not long unknown to the Romans. Silk was brought them from *Serica*, where the worm was a native. But so far were they from profiting by the discovery, that they could not be induced to believe so fine a thread should be the work of a worm, and thereupon formed a thousand chimerical conjectures of their own.

Silk was a very scarce commodity among them for many ages; it was even sold weight for weight with gold, inasmuch that Vopiscus tells us, the emperor Aurelian, who died A. D. 275, refused the empress, his wife a suit of silk, which she solicited of him with much earnestness, merely on account of its dearth.

Others, however, with greater probability, assert that it was known at Rome so early as the reign of Tiberius, about A. D. 17.

Galen, who lived about the year of our Lord 173, speaks of the rarity of silk; being nowhere but at Rome, and only among the rich.

Heliogabalus, the emperor, who died A. D. 220, is said by some to be the first person who wore a holosericum, i. e. a garment of all silk.

The Greeks of Alexander the Great's army are said to have been the first who brought wrought silk from Persia into Greece, about 323 years before Christ; but the manufacture of it was confined to Berytus and Tyre, in Phœnicia, whence it was dispersed over the West.

At length, two monks, coming from the Indies to Constantinople, in 555, under the encouragement of the emperor Justinian, brought with them great quantities of silk-worms, with instructions for the hatching of their eggs, rearing and feeding the worms, and drawing out the silk, and spinning and working it. Upon this, manufactures were set up at Athens, Thebes, and Corinth. The Venetians, soon after this time, commencing a commerce with the Greek empire, supplied all the western parts of Europe with silks for many centuries; though sundry kinds of modern silk manufactures were unknown in those times, such as damasks, velvets, sattins, &c.—About 1130, Roger II. king of Sicily established a silk-manufactory at Palermo, and another in Calabria; managed by workmen, who were a part of the plunder brought from Athens, Corinth, &c. where that prince made a conquest in his expedition to the Holy Land. By degrees, Mezeray adds, the rest of Italy and Spain learned, from the Sicilians and Calabrians, the management of the silk-worms, and the working of silk; and at length the French got it by right of neighbourhood, a little before the reign of Francis I. and began to imitate them. Thuanus, indeed, in contradiction to most other writers, makes this manufacture of silk to be introduced into Sicily 200 years later, by Robert the Wise, king of Sicily, and count of Provence.

It appears, by 33 Henry VI. cap. 5. that there was a company of silk-women in England so early as the year 1455. But these were probably employed in needle-works of silk and thread; and we find that various sorts of small haberdashery of silk were manufactured here in 1482: but Italy supplied England, and all other parts, with the broad manufacture, till the year 1489. In Spain, indeed, the culture and manufacture of silk seem to have been introduced in an early period by the Moors, particularly in Murcia, Cordova, and Granada. The silk manufactures of this last town were very flourishing, when it was taken by Ferdinand, &c. at the close of the 15th century.

In 1521, the French, being supplied with workmen from Milan, commenced a silk manufacture; but it was long after this time before they could obtain raw silk from the worms; and, even in the year 1547, silk was scarce and dear in France; and Henry II. is said to have been the first who wore a pair of silk knit stockings, though the first invention originally came from Spain, whence silk stockings were brought over to Henry VIII. and Edward VI. After the civil wars.

in France, the plantations of mulberry-trees were greatly encouraged by Henry IV. and his successors; and the produce of silk is at this day very considerable.

The great advantage which the new manufacture afforded, made our king James I. very earnest for its being introduced into England: accordingly, it was recommended several times from the throne, and in the most earnest terms, particularly in the year 1608, to plant mulberry-trees, &c. for the propagation of silk-worms, but unhappily without effect; though, from the various experiments we meet with in the Philosophical Transactions, and other places, it appears that the silk-worm thrives and works as well, in all respects, in England as in any other part of Europe.

However, towards the latter end of this king's reign, i. e. about the year 1620, the broad-silk manufacture was introduced into this country, and profecuted with great vigour and advantage. In 1629, the silk manufacture was become so considerable in London, that the silk-throwsters of the city and parts adjacent were incorporated under the name of *masters, wardens, &c. of the silk-throwsters*; and in 1661, this company of silk-throwsters employed about 40,000 persons. The revocation of the edict of Nantes, in 1685, contributed in a great degree to promote the silk manufacture in this kingdom; as did also the invention of the silk-throwing machine at Derby, in 1719.—So high in reputation was the English silk manufacture, that even in Italy, as Keyser informs us, in 1730, the English silks bore a higher price than the Italian.

SILK, Raw, is that taken from the ball, without fire, and wound without any coction: such as is most, if not all, that is brought into England from the Levant; i. e. from Persia by the way of Turkey, from Bengal in India, and from China. The raw silk is commonly worked up into two sorts, called *organzine* and *tram*. The former is made by giving a throw or twist to each thread of raw silk singly, and then doubling two of these twisted threads together, and twisting them smartly together: this forms the length or warp of a piece when manufactured. The tram, or shoot, which makes the breadth of the piece, is formed by twisting two or more threads of raw silk slack. The wasted silk, or refuse in reeling, &c. is collected, carded, and spun, and called *flysilk*; this is doubled and thrown, and often made into a cheap sort of silk stockings, which are very strong and durable.

In the French silk-works, the greatest part of this raw silk passes for little better than a kind of fine florretta; yet, when spun, it makes a bright thread, and serves for the manufacture of stuffs of moderate value and lustre. But the raw silks of the Levant, whence most of ours come, are exceeding fine and beautiful. The difference arises hence, that, in France, the best balls are spun and wound in boiling water, and only the refuse made into raw silk; whereas, in the Levant, there is no such thing as spinning or winding on the fire, but the silks are all sent in bales, or packs, as they are drawn from off the balls; so that they are only distinguished by their quality of fine, middling, and coarse.

SILK, Boiled, is that which has been boiled in water,

to facilitate the spinning and winding. This is the finest of all the sorts of silk manufactured in France, and is seldom used but in the richest stuffs, as velvets, taffaties, damasks, brocades, &c.

There is also another kind of boiled silk, which is prepared by boiling, to be milled, and which cannot receive that preparation without being first passed through hot water. By the laws of France, it is prohibited to mix raw with boiled silk; both as such a practice spoils the dyeing, and as the raw silk corrupts and cuts the boiled.

SILKS, Thrown or Twisted, are such as, beside their spinning and winding, have received their milling or throwing.

This they receive in a different degree, as they are passed oftener or seldomer over the mill; properly, however, thrown silks are those wherein the threads are pretty thick thrown, and twisted several times.

The thrown silk comes to us chiefly from Leghorn, Genoa, Naples, and Messina.

SILKS, Slack, are such as are not twisted, but are prepared, and dyed, for tapestry, and other works with the needle.

SILK, Eastern or East Indian. That popularly thus called is not the work of the silk-worms, but comes from a plant that produces it, in pods, much like those of the cotton-tree. The matter this pod contains is extremely white, fine, and moderately glossy: it spins easily, and is made into a kind of silk that enters the manufacture of several Indian and Chinese stuffs.

SILKS, French. It is only in the most southern provinces of France that silk is cultivated, mulberry-trees planted, and worms bred. The principal places are Languedoc, Dauphiné, Provence, Avignon, Savoy, and Lyons. This last place, indeed, furnishes very few silks of its own growth; but it is the great staple whence the merchants of Paris, and the other cities, are to fetch them. At least, they are obliged to have them pass through Lyons, if they bring them from other places, either by land or sea. There have been computed to enter Lyons, *communibus annis*, 6000 bales, the bale valued at 160 pounds weight; of which 6000 bales there are 1400 from the Levant, 1600 from Sicily, 1500 from Italy, 300 from Spain, and 1200 from Languedoc, Provence, and Dauphiné.

At the time when the manufactures of Lyons were in their prosperity, there were reckoned to be 18000 looms employed in the silk manufacture; but in 1698 there were not reckoned 4000. However, this manufacture has revived of late, and a great part of Europe has been supplied from thence with brocade and rich silks. The decay has not been less notable at Tours: they had formerly there 800 mills for winding and preparing the silks, 8000 looms to weave them, and 40,000 persons employed in the preparation and manufacturing thereof; but these have been reduced to 70 mills, 1200 looms, and about 4000 persons.

SILKS, Sicilian. The commerce of the silks of Sicily is very considerable: and the Florentines, Genoese, and Luccese, are the people who chiefly make it. Great quantities are yearly brought thence, especially from Messina: part whereof they use in their own manufactures, and sell the rest to their neighbours, the French, &c. with profit. The Italians have this advantage, especially the Genoese, over other people, that,

that, having larger establishments in the island, they are reputed as natives, and pay no duty for the export.

Part of the Sicilian silks are raw, the rest are spun and milled; of which last kind, those of St Lucia and Messina are the most valued. The raw unwrought silks are always sold for ready money: the others, sometimes, in exchange for other goods.

SILKS, Italian. The silks brought from Italy are partly wrought, and partly raw and unwrought. Milan, Parma, Lucca, and Modena, furnish none but the latter kind; Genoa most of the former; Bologna affords both kinds. The finest Italian wrought silk comes from Piedmont, Novi, Bergamo, and Bologna: and is imported into England from the ports of Nice, Genoa, and Leghorn.

The silk we have from Italy is generally thrown, and serves for warp for our manufactures: and the greater part we import from Piedmont, at an annual expence of no less than 200,000*l.* and in general at the price of 20*s.* for every pound. And the king of Sardinia, it is said, hath prohibited the exportation of raw silk out of his dominions; though the markets are open in other parts of Italy.

SILKS, Spanish, are all raw; and are spun, milled, &c. in England, according to the several works they are to be used in.

SILKS, Turkey, are all raw. One advantage we have in the commerce of the Levant, in silks, wanting in those of Sicily, is, that the latter are confined to a particular season of the year; whereas the former are bought at all times. They are brought from Aleppo, Tripoli, Sayda, and from the isle of Cyprus, Candia, &c. But the principal place of commerce, especially for the silks of Persia, is Smyrna. The silks are brought hither in caravans, from the month of January to September. The caravans in January are laden with the finest silks; those of February and March bring indifferent ones; the rest, the coarsest. They all come from the several provinces of Persia, chiefly those of Ghilan and Shirvan, and the city of Schamachia, situate near the edge of the Caspian sea; from which three places, a Dutch author assures us, there have not come less than 30,000 bales of silk in a year. Ghilan produces the best and greatest quantities of silk; next to this comes Shirvan and Erivan, then Mazanderan, and lastly Astrabad; but the latter is much inferior, serving only for a manufacture mixed with cotton; that of Mazanderan and Astrabad is seldom or never exported.

Ardeuil, or Ardabil, another city of Persia, not far distant from these silk countries, is the place where silks are laid up, and whence the caravans set out for Smyrna, Aleppo, Scanderoun, and Constantinople; and it is this city, with Schamachia, that have always been esteemed the centre of the silk trade; which has been several times attempted to be removed from Smyrna and the Mediterranean, in favour of Archangel, and the White-sea, by carrying them across Muscovy, by the Volga and Dwina, two rivers that traverse the principal provinces of that vast empire.

This new course of the Persian silks into Europe was first proposed by Paolo Centurio, a Genoese, to the czar Basil, under the pontificate of Leo X. The French had the same design in 1628. The duke of Holstein, in 1633, sent ambassadors to the court of Persia, purely with the same view: and, in 1668, the

czar Alexis Michael attempted the thing himself; but he was disappointed by the rebellion of the Cossacks, and the furprise of Astracan.

In 1688, the commerce of Persian silks had like to have been removed from Smyrna, by an earthquake, which almost overturned the whole city; and doubtless, the removal had been effected, but for the vigorous means used by the Turks to prevent it. Smyrna, however, still remains in her ancient possession; and the several nations of Europe continue every year to send their fleets to fetch away the silks; and matters are like to remain so, unless the conquests made by the late czar, along the Caspian sea, enable his successors, as it is certain he himself had such a thing in view, to put this trade into another channel.

SILKS, China, Japan, and Indian. Several provinces of China are so fertile in mulberry-trees, and their climate is so agreeable to the nature of silk-worms, that the quantity of silk there produced is incredible: the single province of Tcheliang might supply all China, and even a great part of Europe, with this commodity. The silks of this province are the most esteemed, though those of Nankin and Canton be excellent.

The silk-trade is the principal in China, and that which employs the most hands: but the European merchants, who deal in it, especially in wrought silks, are to be careful of the spinning, &c. the waste being usually very great, as the French East India company have found to their cost.

In the year 1750, an act of parliament was passed for repealing the duties payable on China raw silk, imported into this kingdom by the East India Company, and intitling such silk, upon exportation, to the same drawbacks and allowances with the raw silk of the produce of Italy. And another act was passed in 1753, for the farther encouragement of the British silk manufacture. Japan would not afford fewer silks than China; but that the Japanese, a barbarous and distrustful people, have interdicted all commerce with strangers, especially with Europeans, excepting with the Dutch; who are said to be admitted on certain impious terms, related by Tavernier, but which we must own we cannot credit. The Dutch have endeavoured to vindicate themselves from these by the pens of several famous writers.

The silks of the states of the Great Mogul are brought in great quantities from Cassim-bazaar, a midland place, whence they are conveyed by a canal of 15 leagues into the Ganges, by which they are forwarded 15 leagues farther, to the mouth of the famous river of Indostan. The silk of Cassim-bazaar is yellowish; as are also those of Persia and Sicily; there being none, that we know of, naturally white, but that of Palestine. The Indians, however, whiten this with a ley, made of the ashes of a tree called *Adam's fig-tree*; but as this tree is pretty scarce, and they have not yet found any other that will serve in its place, the Europeans are forced to take the greatest part of their silks in their native yellow. Cassim-bazaar alone is computed to furnish every year 22,000 bales of silk, each bale weighing 100 pounds; of which the Dutch are said to export 7000 bales annually.

Great quantities of both raw and wrought silk are
fur-

furnished by other parts of Bengal, and by several provinces of Indostan, which partly supply the natives, and afford a very considerable exportation to Europe. Several thousand bales of raw silk are annually imported from Bengal and China; some of which is, in this state, used for making princely-stuffs, but the greater part is prepared for the manufacturers by the silk-throwers. The duty on thrown silk imported is 5s. 1d. $\frac{1}{2}$; and the duty on raw silk, whether of the growth of Italy, Turkey, or India, is 1s. 4d. $\frac{1}{2}$ per pound.

The quantity of Bengal and China raw silk imported in 1783, was 3636 Bengal bales, each bale weighing about 150 great pounds, and 1390 China bales, at about 145 small pounds per bale.

SKATING, an exercise on ice, both graceful and healthy. Although the ancients were remarkable for their dexterity in most of the athletic sports, yet skating seems to have been unknown to them. It may be looked on, therefore, as a modern invention; and probably it derived its origin in Holland, where it naturally became habitual and necessary, not only as a graceful and elegant amusement, but as an expeditious mode of travelling when the lakes and canals were frozen up during winter. In Holland long journeys are made upon skates with ease and expedition; but in general less attention is there paid to graceful and elegant movements, than to the expedition and celerity of what is called *journey skating*. It is in those countries alone where it is considered as an amusement, that graceful attitudes and movements can be found; and there is no exercise whatever better calculated to set off the human figure to advantage. The acquirement of most exercises may be attained at an advanced period of life; but to become an expert skater, it is necessary to begin the practice of the art at a very early age. It is difficult to reduce the art of skating to a system. It is principally by the imitation of a good skater, that a young practitioner can form his own practice. The English, though often remarkable for feats of agility upon skates, are very deficient in the article of grace; which is partly owing to the construction of the skates, which are too much curved in the surface which embraces the ice, consequently they involuntarily bring the users of them round on the outside upon a quick and small circle; whereas the skater, by using skates of a different construction, less curved, has the command of his stroke, and can enlarge or diminish the circle according to his own wish and desire. The metropolis of Scotland has produced more instances of elegant skaters, than perhaps any other country whatever; and the institution of a Skating Club about 40 years ago, has contributed not a little to the improvement of this elegant amusement. We are indebted for this article to a gentleman of that Club, who has made the practice and improvement of skating his particular study; and as the nature of our work will not permit the insertion of a full treatise on skating, we shall give a few instructions which may be of use towards the attainment of the art.—Those who wish to be proficient should begin at an early period of life; and should first endeavour to throw off the fear which always attends the commencement of an apparently hazardous amusement. They will soon acquire a facility of moving on the inside: and when they do so,

they must endeavour to acquire the movement on the outside of the skates; which is nothing more than throwing themselves upon the outer edge of the skate, and making the balance of their body tend towards that side, which will necessarily enable them to form a semicircle. In this, much assistance may be derived from placing a bag of lead-shot in the pocket next to the foot employed in making the outside stroke, which will produce an artificial poise of the body, which afterwards will become natural by practice. At the commencement of the outside stroke, the knee of the employed limb should be a little bended, and gradually brought to a rectilinear position when the stroke is completed. When the practitioner becomes expert in forming the semicircle with both feet, he is then to join them together and proceed progressively and alternately with both feet, which will carry him forward with a graceful movement. Care should be taken to use very little muscular exertion, but that the impelling motion should proceed from the mechanical impulse of the body thrown into such a position as to regulate the stroke. At taking the outside stroke, the body ought to be easily thrown forward, the unemployed limb kept in a direct line with the body, and the face and eyes directly looking forward: the unemployed foot ought to be stretched towards the ice, with the toes in a direct line with the leg. In the time of making the curve, the body must be gradually, and almost imperceptibly, raised, and the unemployed limb brought in the same manner forward; so that, at finishing the curve, the body will bend a small degree backward, and the unemployed foot will be about two inches before the other, ready to embrace the ice and form a correspondent curve. The muscular movement of the whole body must correspond with the movement of the skate, and should be regulated so as to be almost imperceptible to the spectators. Particular attention should be paid in carrying round the head and eyes with a regular and imperceptible motion; for nothing so much diminishes the grace and elegance of skating as sudden jerks and exertions, which are too frequently used by the generality of skaters. The management of the arms likewise deserves attention. There is no mode of disposing of them more gracefully in skating outside, than folding the hands into each other, or using a muff.

There are various feats of activity and manœuvres used upon skates; but they are so various as to render their insertion too tedious. Moving on the outside is the primary object for a skater to attain; and when he becomes an adept in that, he will easily acquire a facility in executing other branches of the art. There are few exercises but will afford him hints of elegant and graceful attitudes. For example, nothing can be more beautiful than the attitude of drawing the bow and arrow whilst the skater is making a large circle on the outside: the manual exercise and military salutes have likewise a pretty effect when used by an expert skater.

SOLANDER (Dr Daniel Charles), was a native of Sweden, and educated at the university of Upsal, where he obtained the degree of Doctor of Medicine. That of Doctor of Laws was afterwards conferred upon him by the university of Oxford. Dr Solander's strong propensity for the pursuit of natural knowledge was probably

probably not a little increased by the patronage and encouragement of his preceptor the celebrated Sir Charles Linnaeus; while the zeal which he showed for these branches of literature, particularly for botany, conciliated the esteem and affection of that eminent professor. When Dr Solander went from Upsal to London in the prosecution of his studies, Linnaeus furnished him with introductory letters to those learned men who were his principal correspondents in the metropolis of Britain. In these letters, among other strong expressions of regard, he is said to have employed the following sentence: *Omnium discipulorum, quos unquam habui, dilectissimus*. The footing thus obtained, Dr Solander soon improved by agreeable manners and extensive knowledge. In no long time he contracted intimacies with the most eminent philosophers in London, particularly with Sir Joseph Banks, the president of the Royal Society and one of the first literary characters in Europe. He was the companion of Sir Joseph in those different voyages which he made for the sole purpose of extending natural knowledge, and which will do immortal honour to the memory of both. When he was not thus engaged, his time was principally spent in the British Museum, where he had obtained an appointment in every respect suited to his philosophical disposition: and in discharging that part of the duties of his office which led him to show that most valuable collection to different visitors, it was hardly possible to conceive a more agreeable union of the manners of the gentleman with the knowledge of the philosopher. While he was engaged in conversation with his usual cheerfulness at the house of his friend Sir Joseph Banks, he was suddenly attacked with a fit of apoplexy, which in a few days, notwithstanding the best medical assistance, terminated in his death; an event sincerely regretted by all who had the honour of his acquaintance, and by which the literature and philosophy of London sustained a real loss.

SPHEX, the **ICHNEUMON WASP** or **SAVAGE**; a genus of insects belonging to the order of hymenoptera. The mouth is armed with jaws, but without any tongue. The wings of both sexes are extended without folds, and laid horizontally on the back. The sting is sharp, and concealed within the abdomen. The genus is divided into two families. 1. Those in which the abdomen is petiolated, or joined to the thorax by a stalk. 2. Those in which the abdomen is subfissile, or nearly of an equal size through its whole length. The manner of living is different in the various species, and so is the general form of the body and their haunts: but though the method of life be utterly different, yet the same manners appear innate and inherent in all. They agree in being the fiercest of all flies: they will attack insects much larger than themselves, and this whether they be defenceless or armed, as they are provided with a sting. The strength in all this savage kind is great; their jaws are hard and sharp, and in their sting lies a poison suddenly fatal to the creatures with whom they engage. The savage seizes hardily on the animal he attacks, and gives a stroke of amazing force; after which he falls down, as if himself were killed, but it is to rest from his fatigue and enjoy his victory. He keeps a steady eye on the creature he has struck till it dies, which happens in a few minutes, and then drags it to the nest to

feed the young. The number of other insects they destroy is scarce to be conceived; the mouth of their cave is like that of a giant in the days of yore, fraught with the remains of prey. The eyes, the filament that serves as a brain, and a small part of the contents of the body, are all the savage eats, and will kill fifty for a meal.

SPHINX, in zoology, a genus of insects belonging to the order of lepidoptera. There are seven species, all of them commonly called *moths* of different kinds. The name of *sphinx* is given them on account of the singular attitude of their caterpillars, who apply the hinder part of their body to a branch of a tree, holding the rest of it erect, like the fabulous sphinx. Most of them spin their cod under ground, making them up with small parcels of earth and grains of corn interwoven with threads. The sphinges fly either early in the morning or after sunset in the evening. They fly heavily and sluggishly, often emitting a kind of sound. One species, the atropos, or jessamine hawk-moth, has the thorax marked somewhat like a death's head. It has a shrill voice, more dismal than the squeaking of a mouse. All the species suck the nectar of flowers, though they seldom settle upon them.

SPIRIT OF WINE, the same with rectified spirit or alcohol. See **DISTILLATION**.

SPLACHNUM, in botany, a genus of the cryptogamia musci. There are two species.

1. The **ampullaceum**, or **crowet splachnum**, is found in bogs and marshes, and often upon cow-dung. It grows in thick tufts, and is about two inches high. The leaves are oval-lanceolate, terminated with a long point or beard. The top of the filament or peduncle swells into the form of an inverted cone, which Linnaeus terms an *apophysis* or *unbraculum*; upon the top of which is placed a cylindrical anthera, like the neck of a crowet. The calyptra is conical, and resembles a small extinguisher.

2. The **vasculosum**, or **acorn-shaped splachnum**, is found upon bogs and cow-dung, and upon the points of rocks on the tops of the Highland mountains, as on Ben-Lomond, and in the Isle of Sky, and elsewhere. This differs little from the preceding, and perhaps is no more than a variety. The filaments are about an inch high. The leaves oval-acute, not so lanceolate and bearded as the other. The *apophysis*, and the anthera at the top of it, form together nearly an oval figure, not unlike an acorn in its cup, the *apophysis* being transversely femioval and of a blood-red colour, the anthera short and conical. The calyptra is the same as that of the other. The operculum is short and obtuse, and the rim of the anthera has eight large horizontal cilia. The anthera of the other is also ciliated, but not so distinctly. It is an elegant moss, and very distinguishable on account of its orange-coloured filaments and dark-red capsules.

SQUATT, among miners, a small bed of ore, less valuable than a vein or load, as reaching only a little way.

STANHOPE (Dr George), an eminent divine, was born at Hertlihorn in Derbyshire, in the year 1660. His father was rector of that place, vicar of St Margaret's church in Leicester, and chaplain to the earls of Chesterfield and Clare. His grandfather Dr George Stanhope was chaplain to James I. and

Sphinx
||
Stanhope.

Stanhope. Charles I.; had the chancellorship of York, where he was also a canon-residentiary, held a prebend, and was rector of Weldrake in that county. He was for his loyalty driven to doors with eleven children; and died in 1644. Our author was sent to school, first at Uppingham in Rutland, then at Leicester; afterwards removed to Eaton; and thence chosen to King's college in Cambridge, in the place of W. Cleaver. He took the degree of B. A. in 1681; M. A. 1685; was elected one of the fyndics for the university of Cambridge, in the business of Alban Francis, 1687; minister of Quoi near Cambridge, and vice-proctor 1688; was that year preferred to the rectory of Tring in Hertfordshire, which after some time he quitted. He was in 1689 presented to the vicarage of Lewisham in Kent by lord Dartmouth, to whom he had been chaplain, and tutor to his son. He was also appointed chaplain to king William and queen Mary, and continued to enjoy that honour under queen Anne. He commenced D.D. July 5. 1697, performing all the offices required to that degree publicly and with great applause. He was made vicar of Deptford in 1703; succeeded Dr Hooper as dean of Canterbury the same year; and was thrice chosen prolocutor of the lower house of convocation. His uncommon diligence and industry, assisted by his excellent parts, enriched him with a large stock of polite, solid, and most useful learning. His discourses from the pulpit were equally pleasing and profitable; a beautiful intermixture of the clearest reasoning with the purest diction, attended with all the graces of a just elocution. The good Christian, the solid divine, and the fine gentleman, in him were happily united. His conversation was polite and delicate, grave without preciseness, facetious without levity. His piety was real and rational, his charity great and universal, fruitful in acts of mercy, and in all good works. He died March 18. 1728, aged 68 years; and was buried in the chancel of the church at Lewisham. The dean was twice married: 1. to Olivia Cotton, by whom he had one son and four daughters. His second lady, who was sister to Sir Charles Wager, survived him, dying October 1. 1730, aged about 54. One of the dean's daughters was married to a son of bishop Burnet. Bishop Moore of Ely died the day before queen Anne; who, it has been said, designed our dean for that see when it should have become vacant. Dr Felton says, "The late dean of Canterbury is excellent in the whole. His thoughts and reasoning are bright and solid. His style is just, both for the purity of the language, and for the strength and beauty of expression; but the periods are formed in so peculiar an order of the words, that it was an observation, nobody could pronounce them with the same grace and advantage as himself." His writings, which are an inestimable treasure of piety and devotion are, "A Paraphrase and Comment upon the Epistles and Gospels," 4 vols, 1705, 8vo. "Sermons at Boyle's Lectures," 1706, 4to. "Fifteen Sermons," 1700, 8vo. "Twelve Sermons on several occasions," 1727, 8vo. "Thomas à Kempis," 1696, 8vo. "Epictetus's Morals, with Simplicius's Comment, and the Life of Epictetus," 1700, 8vo. "Parson's Christian Directory," 1716, 8vo. "Rocheffoucault's Maxims," 1706, 8vo. "A Funeral Sermon on Mr Richard Sare Bookseller," 1724; two editions 4to. "Twenty Sermons," pub-

lished singly between the years 1692 and 1724. "Private Prayers for every Day in the Week, and for the several Parts of each Day: translated from the Greek Devotions of Bishop Andrews, with Additions, 1730." In his translations, it is well known, Dr Stanhope did not confine himself to a strict and literal version: he took the liberty of paraphrasing, explaining, and improving upon his author; as will evidently appear (not to mention any other work) by the slightest perusal of St Augustine's Meditations, and the Devotions of Bishop Andrews.

STEPHENS'S MEDICINES for the STONE, were only a more imperfect method of using soap-ley in that distemper. See **CHITTRICK**.

STERNWAY, is when a ship, instead of advancing, retreats in the water, either through the violence of a current or any other means.

STONE-CHATTERER, (*Motacilla Rubicola*), in ornithology, a species omitted to be described under **MOTACILLA**. It is common among us during summer in garly grounds. In the winter they disperse into marshes and other places, but do not quit the island. It is a restless and noisy bird, and perches frequently on some bush, chattering incessantly. The head, neck, and throat, are black; but on both sides of the latter is a white bar, so that it appears on first sight to be encircled with white; the feathers on the back are black, edged with tawny; the lower part of the back just above the rump is white: the end and exterior side of the two outmost feathers of the tail are of a pale rust-colour, the rest are black: the breast is of a deep reddish yellow; the belly of a lighter hue: the quill-feathers are dusky edged with dull red; those next the body are marked with a white spot near their bottoms; the coverts of the wings are adorned with another. The head of the female is ferruginous spotted with black; and the colours in general are less vivid. In both sexes the legs are black.

SULZER (M.), a celebrated philosopher, was born at Winterthur, in the canton of Zurich, October 16. 1720. He was the youngest of 25 children. His early education did not promise much, though it was by no means neglected. He had little inclination for what is called in the schools the study of humanity, and made but a small progress in the learned languages, which were to prepare him for the study of theology, for which profession his parents designed him. At the age of 16, when he went to the academical school of Zurich, he had not the smallest notion of the sciences, or of elegant literature, and consequently no taste for study. The first incident that developed a hidden germ of philosophical genius, was his meeting with Wolfe's metaphysics: this was the birth of his taste for science; but he wanted a guide. The clergyman with whom he lodged was an ignorant man; and the academical prelections were, as yet, above the reach of his comprehension. On the other hand, a sedentary life was not the thing he liked, nor to which he had been accustomed; and, moreover, a sociable turn of mind led him often into company, where he lost much time in frivolous amusements, yet without corrupting his morals. Who, that observed him at this period, says Mr Formey in his *Eulogium*, would have thought that Sulzer would one day be numbered among the most knowing and wisest men of his time? The learned

Gesner

Gefner was the instrument of Providence that rendered Sulzer's inclination to study triumphant over his passion for amusement and company. Animated by the counsels and example of this worthy and learned man, he applied himself to philosophy and mathematics with great ardour, and resumed the pursuit of Grecian literature and the Oriental languages. The contemplation of nature became his noble and favourite passion. An ecclesiastical settlement in a rural scene, that exhibited happy objects and occasions for this delightful study, began to render his days happy and useful; and he published, in 1741, *Moral Contemplations of the works of Nature*; and, the year following, an *Account of a voyage* he had made through the Alps; which showed, at the same time, his knowledge of natural history, and the taste and sensibility with which he surveyed the beauties of nature, and the grandeur and goodness of its author. He afterwards became private tutor to a young gentleman at Magdeburg. This procured him the acquaintance of Messrs Maupertuis, Euler, and Sack, which opened to his merit the path of preferment, and advanced him successively to the place of mathematical professor in the King's College at Berlin in 1747, and to that of member of the Royal Academy in 1750.

In this last quality he distinguished himself in a very eminent manner, enriched the class of speculative philosophy with a great number of excellent memoirs, and was justly considered as one of the first-rate metaphysicians in Germany. But his genius was not confined to this branch of science. His *Universal Theory of the Fine Arts*, is a capital production. A profound knowledge of the arts and sciences, and a perfect acquaintance with true taste, are eminently displayed in this work, and will secure to its author a permanent and distinguished rank in the republic of letters. The first volume of this excellent work was published in 1771, and the second in 1774. We shall not here give a catalogue of the writings of M. Sulzer; but we cannot help mentioning his *Remarks on the Philosophical Essays* of the late Mr Hume, as a work of real merit, which does justice to the acuteness, while it often detects the sophistry, of the British Bayle. The moral character of M. Sulzer was amiable and virtu-

ous: sociability and beneficence were its characteristic lines; and his virtues were animated by that sacred philosophy that forms the Christian, ennobles man, and is the only source of that heart-felt serenity and sedate fortitude which support humanity, when every other object of confidence fails. His dying moments were calm, humble, and sublime; and when he expired, the placid and composed air of his countenance made his mourning friends doubt, for some time, whether it was death or sleep that had suspended his conversation. He had no enemy; and his friends were numerous, affectionate, and worthy of the tender returns he made them.

The king of Prussia distinguished him by repeated marks of munificence and favour. We learn, however, that his royal protector had never seen him before the end of the year 1777, tho' he had been member of the academy from the year 1750. The audience, indeed, though late vouchsafed, was honourable to M. Sulzer, with whom the monarch conversed for a long time with the greatest affability and condescension.

SYNCOPATION, in music, denotes a striking or beating of time, whereby the distinction of the several times or parts of the measure is interrupted.

However, it is more properly used for the connecting the last note of any measure, or bar, with the first of the following measure; so as only to make one note of both.

A Syncope is sometimes also made in the middle of a measure.

Syncopation is also used when a note of one part ends or terminates on the middle of a note of the other part. This is otherwise denominated *binding*.

It is likewise used for a driving note; that is, when some shorter note at the beginning of a measure, or half measure, is followed by two, three, or more longer notes before another short note occurs, equal to that which occasioned the driving, to make the number even, *e. gr.* when an odd crotchet comes before two or three minims, or an odd quaver before two, three, or more crotchets.

In syncopated or driving notes, the hand or foot is taken up, or put down, while the note is sounding.

T.

TAGETES, FRENCH MARGOLD; a genus of the polygamia superflua order, belonging to the syncopata class of plants. There are three species; the most remarkable are,

1. The erecta, grows naturally in Mexico, but has been long cultivated in the British gardens, where it is commonly titled *African margold*. Of this there are the following varieties: 1. Pale yellow, or brimstone colour, with single, double, and fistulous flowers.
2. Deep yellow, with single, double, and fistulous flowers.
3. Orange-coloured, with single, double, and fistulous flowers.
4. Middling African, with orange-coloured flowers.
5. Sweet-scented African. These are all very subject to vary; so that unless the seeds are very carefully saved from the finest flowers, they are apt to degenerate: nor should their seeds be too long sown in the same garden without changing

for the same reason; therefore, those who are desirous to have these flowers in perfection, should exchange their seeds with some person of integrity at a distance where the soil is of a different nature, at least every other year. If this is done, the varieties may be continued in perfection. This plant is so well known as to need no description. It flowers from the beginning of July till the frost puts a stop to it.

2. The patula, grows naturally in Mexico, but has been long in the British gardens, where it is distinguished from the first by the title of *French margold*. Of this there are several varieties, some of which have much larger flowers than others, and their colour varies greatly: there are some which are beautifully variegated, and others quite plain; but as these are accidents arising from culture, so

Tavira,
Tea.

so they do not merit farther distinction; for we have always found that seeds sowed from the most beautiful flowers will degenerate, especially if they are sown in the same garden for two or three years together, without changing the seed.

These plants are annual, so must be propagated from seeds every spring, which may be sown upon a moderate hot-bed the beginning of April: and when the plants are come up, they should have plenty of fresh air; for if they are drawn too much, they will not afterward become handsome, notwithstanding they have all possible care taken of them. When they are about three inches high, they should be transplanted on a very moderate hot-bed, which may be arched over with hoops and covered with mats, for these plants are hardy enough to be brought up without glasses: in this bed they should be planted about six inches asunder each way, observing to water and shade them until they have taken root; but as the plants acquire strength, they should be inured to bear the open air by degrees; and about the end of May they should be taken up with a ball of earth to the root of each plant, and planted into the borders of the parterre-garden, or into pots, for furnishing the courts, &c. shading them carefully from the sun till they have taken new root, and also supplying them duly with water. When their flowers appear, if any should prove single, the plants should be destroyed, and then those in pots may be removed to the court, where the several varieties, being intermixed with other annual plants, afford an agreeable variety.

These plants have a strong disagreeable scent, especially when handled; for which reason they are not so greatly esteemed for planting near habitations: but the flowers of the sweet-scented sort being more agreeable, are generally preferred, especially for planting in small gardens.

TAVIRA, or TAVILA, a considerable town of Portugal, and capital of the province of Algarve, with a handsome castle, and one of the best harbours in the kingdom, defended by a fort. It is seated in a pleasant fertile country, at the mouth of the river Gilaon, between Cape Vincent and the Strait of Gibraltar, 100 miles west by north of Cadiz. W. Long. 7. 46. N. Lat. 37. 18.

TEA, (*Encycl.*) Tea, in the Chinese language, is called *tia*, in Fokien it is called *te*; and as the Europeans landed first in that province, that dialect has been preferred.

The Europeans learned to drink this infusion in the 15th century; and since that time have vied with each other in giving the Chinese the most money for this and other goods which are become fashionable: it grows both in China and in Japan. It likewise grows in Tonkin; but the best tea, according to Du Halde, comes from Fokien.

It was universally believed that all teas come from the same shrub, and are only distinguished by the different age, gathering, and preparation, till Doctor Hill lately supposed that he had discovered that the brown tea comes from the tea-shrub with six petals or flower-leaves which Kempfer has described and represented, but that the green tea is taken from the tea-shrub with nine-leaved flowers. Linnæus distin-

guishes it, besides the flowers, by the longer and narrower leaves.

The difference of petals may, however, be considered as dubious, at least as not invariable. See Plate CCCXXIII. where a figure of each is given; that of the bohea being taken from the *Amœn. Acad.* vol. 7.; that of the viridis from a print by Miller after a drawing of a plant, in the duke of Northumberland's garden at Sion, which was the first that flowered in England, and he flower consisted of only six petals, like the bohea. [This last figure is rather upon too small a scale comparatively with the other.]

After all, there are many sorts and varieties of tea differing one from another in the shape and quality of the leaves; and differently denominated, from these circumstances, from the places where they grow, or from the various ways of preparing.

The general distinction of these, however, is into brown and green, according as they tinge the water.

1. Brown Teas.

Brown tea is *bonam té*, or *kuli-té*, which grows in some places about Canton, and is drunk by the Chinese, but not by the Europeans: its taste being the least agreeable of any. The dried leaves are either yellow or brownish. The tea-shrubs, which are sold in flower-pots here, scarce grow to the height of an ell. The flower consists of six white petals, of which the three lowest are the smallest.

An-kay is a coarse sort of tea, from a place of this name.

Té-bohé, which we usually call *bohea-tea*, is called *moji* by the Chinese. This sort is brought to Europe in greater quantities than any of the others. The best sort smells agreeably, and in a short time gives a brown colour to the water, and consists of leaves of one colour; if any black ones are among them, it is a bad sort.

Tao-yonn is the name of the best sort of bohea tea.

Kongo, or as the Chinese call it *kong-so*, has an agreeable scent: its leaves are finer than those of *té-bohé*; though it is scarce distinguishable from the best bohea, except in price; for *kongo* is somewhat dearer.

Sutchong, or *sootchuen*, which the Chinese call *saa-tyang*, or *su-tyann*, is the dearest of all brown teas. It gives a fine yellow green colour to the water, and has an agreeable taste, unless you put too much into the pot, which spoils both taste and colour.

Padre sutchong is the best tea that can be drunk. The leaves of this tea are large, yellowish, not rolled up, but expanded; and packed up in papers of half a pound each, like tobacco. If it is not taken great care of at sea, it is much altered for the worse.

Lin-kiam is a sort of tea which hath narrow rough leaves and footstalks. It is seldom used by itself, but mixed with other sorts.

Back-ho, or *pack ho*, is that which we call *pecks*, which has leaves with dots. It is a mild tea, has a good taste, and is said to be the least heating of any.

2. Of Green Teas, there are

Hysen, called by *tiann*, or *hi-kiong* by the Chinese. *Single*, or *sangle*, is so called from the place whence it comes. The Chinese likewise call it *sing-tia*.

Bing, or imperial tea.

Tia té is rolled up like pease. This sort is rolled up

*Obbeck's
Voyage to

up between the hands in a rounder shape than the others. A smaller kind is called *gunpowder-tea*.

Hyson utchin, is distinguishable from the *hyson skin* by its narrow and short leaves.

Go-bé hath long narrow leaves.

The Chinese likewise make tea-cakes, which they sell very dear.

It is almost incredible what quantities of tea are annually exported into Europe and other parts; and what innumerable hands are employed in so unnecessary an article. The countryman must with great care plant and nurse the tea-shrubs; pluck every leaf in due time; separate the new leaves from the old, and dry them with extreme accuracy. When the merchant has got the baskets of tea, at a low rate, from the country people, he must often take care of it for years together; and is always uncertain when, or at what price, he shall sell it. When the Europeans have fixed upon a place where they will make their bargains, they empty the baskets (but let it be noted we are now speaking of bohea tea, for the finer sorts are sold in chests); and if any bad tea is found in these baskets, it is separated from the rest. The good tea is then packed up in new chests, the weight of which is deducted; and these chests are marked, and lined with lead in the inside. A Chinese gets into these chests, and treads down the tea as it is emptied out of the baskets: this is very hard labour, and throws the treader, who is almost naked, into a profuse perspiration. Though great care is taken to prevent any thing from coming into the tea, yet it is hardly to be avoided: and sometimes their feet are wounded and bleed. But the tea has already passed thro' so many dirty hands, that those who use that drug have no reason to be disgusted with this last mark of indelicacy in the package. As soon as some of the chests are packed by a number of kulcers, or Chinese servants, they are pasted over with paper, and carried out of the warehouse to the factories, where they are weighed by the Chinese custom-house officers, in the presence of the interpreter, and marked red with a stiff brush, or with a wooden stamp.

Some poor people are satisfied with the leaves of rhamnus tea, which they put into their clayey water, instead of tea, to make it more palatable. In the account of the Dutch embassy to China, it is related that the Chinese make use of a species of moss instead of tea.

The high price of tea, at its first introduction, induced many physicians to think of a substitute; and it is well known that Simon Pauli thought the *myrica gale* to be the shrub itself. Other succedanea are mentioned by authors; such as the leaves of the

Prunus spinosa, sloe-tree.

Origanum vulgare, wild marjoram.

Rubus arcticus, arctic bramble.

Veronica officinalis, male speedwell.

Veronica chamaedrys, wild germander.

Chenopodium ambrosioides, Mexican sweet blite.

Capraria biflora, sweet-weed or goat-weed.

The sophistication of tea practised by the smugglers in some of the southern parts of this kingdom is well known. In particular, they have reduced to a regular process the management of the leaves of the ash and elder; which, when prepared, is called *smouch*, and mixed, as is said, in the proportion of one-third,

with the ordinary teas. To what an extent the trade in this sophisticated tea had been carried, to the detriment of the trees, may be imagined, when the reader is informed, that an act of parliament has lately been obtained to prohibit it, under very severe penalties.

THELIGONUM, DOG'S CABBAGE; a genus of the polyandria order, belonging to the monœcia class of plants. There is only one species; viz. the cynocrambe or dog's cabbage of Dioscorides. This plant grows plentifully in the south of France, in Italy and Tartary. It is annual. The stalks trail on the ground like those of chickweed; they grow about a foot long; their joints are pretty close, garnished with oval acute-pointed leaves, standing on pretty long footstalks, which are bordered. At each joint is placed one of these leaves; and from the same point come out several smaller, of the same shape, on shorter footstalks. The flowers are produced from the wings of the stalks in clusters, fitting very close; they are small, of an herbaceous white colour, so make no great appearance. The male and female flowers grow from the same joint. The female flowers are succeeded by a single roundish seed, which ripens in autumn.

It is preserved in botanic gardens for the sake of variety. The seeds of this must be sown in autumn, in the place where the plants are to remain; for when they are sown in the spring, the plants rarely come up the same year. They require no other culture but to keep them clean from weeds, and thin them where they are too close.

THEOBROMA, in botany, a genus of the polydelfia order, belonging to the pentandria class of plants. There are two species, both natives of the Indies.

1. The first, which is the cacao, or chocolate-nut tree, is but of very moderate growth. See **CACAO**, (*Encycl.*) and Plate LXVI.

2. The guazuma, or baltard cedar of Jamaica, rises with an upright large trunk, branching numerously, and spreading 30 or 40 feet high; with oblong, heart-shaped, serrated, alternate leaves, four inches long; and numerous small yellowish flowers at the sides of the branches; succeeded by roundish, tuberculated rough fruit, containing the seed.

TIBERIUS, the third emperor of Rome, under whose reign our Saviour suffered. See **ROME**, n° 268. —281.

TIMBER, (*Encycl.*) Of all the different kinds known in Europe, oak is the best for building; and even when it lies exposed to air and water, there is none equal to it. Fir-timber is the next in degree of goodness for building, especially in England, where they build upon leaves. It differs from oak in this, that it requires not much seasoning, and therefore no great stock is required before-hand. Fir is used for flooring, wainscoting, and the ornamental parts of building within doors. Elm is the next in use, especially in England and France: it is very tough and pliable, and therefore easily worked: it does not readily split: and it bears driving of bolts and nails better than any other wood; for which reason it is chiefly used by wheel-wrights, and coach-makers, for shafts, naves, &c. Beech is also used for many purposes: it is very tough and white when young, and of great strength; but liable to warp very much when exposed to the weather, and to be worm-eaten when used with-

Timber.

in doors; its greatest use is for planks, bedsteads, chairs, and other household goods. Ash is likewise a very useful wood, but very scarce in most parts of Europe; it serves in buildings, or for any other use, when screened from the weather; handspikes and oars are chiefly made of it. Wild chestnut timber is by many esteemed to be as good as oak, and seems to have been much used in old buildings; but whether these trees are more scarce at present than formerly, or have been found not to answer so well as was imagined, it is certain this timber is now but little used. Walnut-tree is excellent for the joiner's use, it being of a more curious brown colour than beech, and not so subject to the worms. The poplar, alder, and aspen trees, which are very little different from each other, are much used instead of fir, they look well, and are tougher and harder.

The goodness of timber not only depends on the soil and situation in which it stands, but likewise on the season wherein it is felled. In this people disagree very much; some are for having it felled as soon as its fruit is ripe, others in the spring, and many in the autumn. But as the sap and moisture of timber is certainly the cause that it perishes much sooner than it otherwise would do, it seems evident that timber should be felled when there is the least sap in it, viz. from the time that the leaves begin to fall till the trees begin to bud. This work usually commences about the end of April in England, because the bark then rises most freely; for where a quantity of timber is to be felled, the statute requires it to be done then, for the advantage of tanning.

The ancients chiefly regarded the age of the moon in felling their timber; their rule was to fell it in the wain, or four days after the new moon, or sometimes in the last quarter. Pliny advises it to be in the very article of the change, which happening to be in the last day of the winter solstice, the timber, says he, will be incorruptible. Timber should likewise be cut when of a proper age; for when it is either too young or too old, it will not be so durable as when cut at a proper age. It is said that oak should not be cut under 60 years old, nor above 200. Timber, however, should be cut in their prime, when almost fully grown, and before they begin to decay; and this will be sooner or later, according to the dryness and moistness of the soil where the timber grows, as also according to the bigness of the trees; for there are no fixed rules in felling of timber, experience and judgment must direct here as in most other cases.

After timber has been felled and sawed, it must be seasoned: for which purpose some advise it to be laid up in a very dry airy place, yet out of the wind and sun, or at least free from the extremities of either; and that it may not decay, but dry evenly, they recommend it to be daubed over with cow-dung. It must not stand upright, but lie all along, one piece over another, only kept apart by short blocks interposed, to prevent a certain mouldiness which they are otherwise apt to contract in sweating on one another; from which arises frequently a kind of fungus, especially if there be any sappy parts remaining. Others advise the planks of timber to be laid for a few days in some pool or running stream, in order to extract the sap, and afterwards to dry them in the sun or air. By this

means, it is said, they will be prevented from either chopping, casting, or cleaving, but against shrinking there is no remedy. Some again are for burying them in the earth, others in a heat; and some for scorching and seasoning them in fire, especially piles, posts, &c. which are to stand in water or earth. The Venetians first found out the method of seasoning by fire; which is done after this manner: They put the piece to be seasoned into a strong and violent flame; in this they continually turn it round by means of an engine, and take it out when it is everywhere covered with a black coaly crust; the internal part of the wood is thereby so hardened, that neither earth nor water can damage it for a long time afterwards.

After the planks of timber have been well seasoned and fixed in their places, care is to be taken to defend or preserve them; to which the smearing them with linseed oil, tar, or the like oleaginous matter, contributes much. The ancients, particularly Hesiod and Virgil, advise the smoke-drying of all instruments made of wood, by hanging them up in the chimneys where wood-fires are used. The Dutch preserve their gates, portcullices, drawbridges, sluices, &c. by coating them over with a mixture of pitch and tar, whereon they strew small pieces of cockle and other shells, beaten almost to powder, and mixed with sea-sand, which incrusts and arms them wonderfully against all assaults of wind and weather. When timber is felled before the sap is perfectly at rest, it is very subject to the worms; but to prevent and cure this, Mr Evelyn recommends the following remedy as the most approved: Put common sulphur into a cucurbit, with as much aquafortis as will cover it three fingers deep; distil it to dregs, which is performed by two or three rectifications. Lay the sulphur that remains at bottom, being of a blackish or sand-red colour, on a marble, or put it in a glass, and it will dissolve into an oil; with this oil anoint the timber which is infected with worms. This, he says, will not only prevent worms, but preserve all kinds of woods, and many other things, as ropes, nets, and masts, from putrefaction, either in water, air, or snow.

TRIBULUS, CALTROPS; a genus of the monogynia order, belonging to the decandria class of plants. There are three species; the most remarkable is the terrestris, with six pair of lobes to each leaf. It is a very common weed in the south of France, in Spain, and Italy, where it grows among corn, and on most of the arable land, and is very troublesome to the feet of cattle; for the fruit being armed with strong prickles, run into the feet of the cattle which walk over the land. This is certainly the plant which is mentioned in Virgil's Georgics under the name of *tribulus*, tho' most of his commentators have applied it to other plants. It is called in English *caltrops*, from the form of the fruit, which resembles those instruments of war that were cast in the enemies way to annoy their horses.— This hath a slender fibrous root, from which spring out four or five slender hairy stalks, which spread flat on the ground, garnished at each joint with winged leaves, composed of six pair of narrow hairy lobes, almost of equal size; those on the lower part of the stalk stand alternately, but toward the top they are placed opposite. The flowers come out from the wings of the stalk, standing upon short footstalks; they are composed

Timber,
Tribulus.

Trill.
tropaeolum.

composed of five broad, obtuse, yellow petals, which spread open. In the centre is situated an oblong germ, crowned by a headed stigma, attended by ten short filamina, terminated by single summits, and are succeeded by roundish, five-cornered, prickly fruit, which, when ripe, divides into five parts, each having a transverse cell containing one or two seeds.—This plant is preferred in botanic gardens for variety. It is propagated by seeds, which should be sown in autumn; for those which are kept out of the ground till spring commonly remain in the ground a whole year before the plants come up. These seeds should be sown on an open bed of light earth, where they are designed to remain; for as it is an annual plant, it doth not bear transplanting very well, unless it be done when the plants are very young. In the spring, when the plants come up, they should be carefully cleared from weeds; and where they come up too close, some of the plants should be pulled out to give room for the remaining plants to grow; after this they will require no other culture but to keep them clear from weeds. If the seeds are permitted to scatter, the plants will come up the following spring, and maintain their place if they are not overborne with weeds.

TRILL, or **PLAIN SHAKE** and **GRUPPO**, in music. The first is defined to be a shake upon one note only, in the making whereof the scholar is directed to sing the first of the examples, (Plate CCCXIII. fig. 2.) beginning with the first crotchet, and beating every note with the throat upon the vowel *o*, to the last breath. The gruppo (as described by Playford) appears to be no other than the shake now practised, and which consists in the alternate prolation of two tones in juxtaposition to each other, with a close on the note immediately beneath the lower of them. The trill (says Playford) being the most usual grace, is made in closes or cadences; and when on a long note, exclamation or passion is expressed there, the trill is made in the latter part of such note; but most usually upon binding notes, and such as precede the closing note. Notwithstanding this, Mr Hawkins is of opinion that the trill is rather a defect than an ornament in singing; as being nothing more than the intermitted prolation of a single tone.

TROPEOLUM, **INDIAN CRESS**; a genus of the monogynia order, belonging to the octandria class of plants. There are two species: 1. The minus, or small Indian cress, grows naturally in Peru. This was first brought to Europe in 1684, and was raised in the gardens of count Bevening in Holland. It has a trailing herbaceous stalk, garnished with leaves almost circular. The foot-stalk is inserted in the centre of the leaf, like a buckler, as in the navelwort; they are smooth, of a greyish colour; the flowers come out from the wings of the stalks, standing upon very long slender foot-stalks, of an admirable structure, composed of five acute-pointed petals; the two upper are large and rounded, the three under are narrow; their tails join together, and are lengthened into a tail two inches long. After the flower is past, the germen turns to a roundish fruit, which is furrowed, and divided into three lobes, each including one streaked seed. It flowers from Midsummer till the frost stops it in autumn. There are two varieties of this, one with a deep orange-coloured flower, inclining to red, and the

other with a pale yellow flower. 2. The majus, or greater Indian cress, grows naturally about Lima; this has larger stalks than the former. The leaves are also larger, and their borders are indented almost into lobes; the flowers are larger, and their petals are rounded at their points. There are two colours of this sort as in the former; and one with double flowers, which is propagated by cuttings, for it does not produce seeds.—The first sort is less common at present in the English gardens than the second, though it was formerly more so; the flowers of the latter being larger, make a finer appearance, for which it is preferred: they are both esteemed annual plants, though they may be continued through the winter if they are kept in pots, and sheltered in a good green-house, in like manner as that with double flowers is preferred; so may be propagated by cuttings as that is. But, as these ripen their seeds constantly every year, the plants are generally raised from them: these may be sown in April in the places where they are to remain, which should be where their stalks may have support; for they will climb six or eight feet high, when they are trained up, and then their flowers make a good appearance; but when they trail upon the ground, they will spread over the neighbouring plants and become unsightly.—The flowers of these plants are frequently eaten in salads; they have a warm taste like the garden cress, and are esteemed very wholesome; they are likewise used for garnishing dishes. The seeds are pickled, and by some are preferred to most kinds of pickles for sauce.

TRYING, in the sea-language. A ship is said to *try* or to *lie a-try*, when no sails are abroad but the main-fail or mizen-fail.

TUBIPORA, or **TUBULARIA**, a genus of submarine plants, belonging to the cryptogamia class, of the hardness of coral, and consisting of cylindric tubes rising from a thin crust of the same sort of matter with themselves. See Plate CCCXVII.

TYLES, (*Encycl.*) There are various kinds of tyles for the various occasions of building; as plain, thack, ridge, roof, crease, gutter, pan, crooked, or Flemish, corner, hip, dormar, scarp, scallop, astragal, traverse, paving, and Dutch tyles.

Plain or thack tyles, are those in ordinary use for covering of houses. They are squeezed flat, while yet soft, in a mould. They are of an oblong figure; and by 17 Edw. IV. c. 4. are to be $10\frac{1}{2}$ inches long, and $6\frac{1}{2}$ broad, and half an inch and half a quarter thick. But these dimensions are not over strictly kept to.—Ridge, roof, or crease tyles, are those used to cover the ridges of houses, being made circular breadthwise, like an half-cylinder; they are, by the aforesaid statute, to be 13 inches long, and of the same thickness with the plain tyles.—Hip or corner tyles, are those which lie on the hips or corners of roofs. As to form, they are first made flat like plain tyles, but of a quadrangular figure, whose two sides are right lines, and two ends edges of circles, one end being a little concave and the other convex. The convex end is to be about seven times as broad as the concave end, so that they would be triangular but that one corner is taken off; then, before they are burnt, they are bent on a mould breadthwise, like ridge tyles. They have an hole at their narrow end to nail them on by, and are laid.

Trying
||
Tyles.

Tyles,
Vayer.

laid with their narrow end upwards; by statute, they are to be 10½ inches long, and of a convenient breadth and thickness.—Gutter tiles, are those which lie in gutters or valleys in cross buildings. They are made like corner-tyles, only the corners of the broad end are turned back again with two wings. They have no holes in them, but are laid with the broad end upwards, without any nailing. They are made in the same mould as the corner-tyles, and have the same dimensions on the convex side. Their wings are each four inches broad and eight long. Pan, crooked, or Flemish tyles, are used in covering of sheds, lean-to's, and all kinds of flat-roof buildings. They are in form of an oblong parallelogram, as plain tyles; but are bent breadthwise forwards and backwards in form of an S, only one of the arches is at least three times as big as the other; which biggest arch is always laid uppermost, and the less arch of another tyle lies over the edge of the great arch of the former. They have no holes for pins, but hang on the laths by a knot of their own ear. They are usually 14½ inches long, and 10½ broad. By 12 Geo. I. c. 25. they are to be, when burnt, not less than 13½ inches long, and 9½ inches wide, and half an inch thick.—Dormar or dorman tyles consist of a plain tyle and a triangular piece of a plain one standing up at right angles to one side of the plain tyle, and swept with an arch of a circle from the other end, which end terminates in a point. Of these tyles there are two kinds, the triangular piece in some standing on the right, in others on the left side of the plain tyle. And of these again there are two kinds, some having a plain whole tyle, others but half a plain tyle. But in them all the plain tyle has two holes for the pins at that end where the broad end of the triangular piece stands. Their use is to be

Tyles,
Vespa.

laid in the gutters betwixt the roof and the cheeks or sides of the dormars, the plain part lying on the roof, and the triangular part standing perpendicularly by the cheek of the dormar; they are excellent to keep out the wet in those places, and yet they are hardly known any where but in Suffex. The dimensions of the plain tyle part are the same as those of a plain tyle; and the triangular part is of the same length, and its breadth at one end seven inches, and at the other nothing. Scallop or atragal tyles are in all respects like plain tyles, only their lower ends are in form of an atragal, viz. a semicircle with a square on each side. They are used in some places for weather-tyling.—Transverse tyles are a kind of irregular plain tyles, having the pin-holes broken out, or one of the lower corners broken off. These are laid with the broken end upwards, upon rafters where pinned tyles cannot hang.

Flemish or Dutch tyles are of two kinds, ancient and modern: the ancient were used for chimney foot-pieces; they were painted with antique figures, and frequently with postures of soldiers, some with compartments, and sometimes with morefque devices; but they come much short of the design and colours of the modern ones. The modern Flemish tyles are commonly used plastered up in the jaumbs of chimneys instead of chimney-corner stones. These are better glazed, and such as are painted (for some are only white) are done with more curious figures and more lively colours than the ancient ones. But both kinds seem to be made of the same whitish clay as our white glazed earthen ware; the modern ones are commonly painted with birds, flowers, &c. The ancient ones are only five inches and a quarter square, and about three quarters of an inch thick; the modern ones six inches and a half square, and three quarters of an inch thick.

U, V.

VAYER (Francis de la Mothe le), a Parisian counsellor of state, and preceptor to the duke of Anjou: only brother to Lewis XIV. was born at Paris in 1588. He was admitted into the French academy in 1639; but his style was less polite than that of his fellow-academicians. He was a man of a regular conduct, like that of the ancient sages; however, his austerity and wisdom did not prevent his being accused of having no religion. This was probably founded on certain Dialogues written by him, and published under the name of *Graſius Tubero*, and upon his showing throughout his works in general too great an inclination to scepticism. He was greatly affected at the loss of his only son; and his grief disordered him so much, that he married again, though he was above 75, and had no reason to lament his first wife. He died in 1672, aged 84.

VESPA, the wasp, in zoology, a genus of insects of the hymenoptera order; of which the following are the characters: The mouth is armed with jaws, but has no rostrum: the upper wings are folded in both sexes: the sting is sharp-pointed, and concealed within the abdomen: the eyes are lunular: the body is smooth, without hair: to which may be added, that the antennæ are broken, the first articulation being longer than the rest; the under wings shorter than the

upper; the abdomen joined to the thorax by a very short stalk; and the stemmata three in number.

1. The crabro, has the antennæ and head of a dun colour, somewhat brown. The upper lip is yellow, and the eyes are blackish. The middle of the thorax is black; brown on the fore-part, the sides, and behind. The legs are of the same brown colour, inclining to chefnut. The first segment of the abdomen is black mixed with brown, and slightly edged with lemon colour; the others are black on the upper side, a portion of which is again covered by the upper segment, and yellow underneath. Upon the yellow are seen two black spots on each of the rings; one on each side, connected with the black colour of the upper part. This large species of wasps makes its nest in the trunks of hollow trees, and in the timber-work of lofts. Its cakes or combs are composed of a substance resembling coarse paper or rusty parchment. It is very voracious, devouring other insects, and even bees. Of those insects, some live in society, others are solitary. A distinguishing character of this genus of flies is their bodies being smooth and apparently without hairs. Their upper wings, when at rest, are folded in two the whole length of them. At the rise of each of those wings is situate a scaly part, which performs the office of a spring to hinder the upper wing from rising

rising too high in the flapping of their wings; a caution very important to those carnivorous insects who pursue their prey on full stretch of wing.

2. The vulgaris, or common wasp. These raise subterraneous buildings, live in associations, feed on plunder, and commit great outrages on our wall-fruit. This numerous commonwealth is founded by a single female impregnated during the autumn, and that has weathered out the severity of the winter. It digs a hole in a dry soil, contrives itself a sinuous inlet, or else it takes up with the dwelling-place of a mole, where it hastily builds a few cells and deposits its eggs. Within the space of 20 days, they have gone through the different states of larvæ, chrysalids, and are turned to wasps. Nature, all-wise, provides for every thing. The mule-wasps, or that are of no sex, are the only ones that labour at laying the foundation of the republic. The first eggs that are hatched prove to be neuter wasps. No sooner are they come into existence, but they fall to work, enlarge the hole, and go about upon wood, lattice-work, and window-sashes, in search of materials for building. With their teeth they cut, hack, and tear off small fibres of wood, which they moisten with a liquor they disgorge, and then convey them to the work-shop. Other labourers are in waiting for them, who with those materials set about the construction of the wasp-nest; an edifice outwardly composed of sheets of paper, which not being in contact with each other, dampness cannot penetrate to the inside. This latter part consists of 12 or 15 stories, and between each runs a colonnade formed by the fastenings which connect the cakes one to the other. Every story is as it were a market-place, where the citizens may take their walks. The cells are hexagonal. It is the cradle in which the mother continues to lay eggs of neuter-wasps to the number of 15000 or 16000; after which it deposits 300 eggs of females, and as many of males. The elder brothers, or first-hatched insects, take amazing care of those born after them, by proportioning their food to the delicacy of their stomach. First, it consists of the juice of fruits and meats, afterwards it is the carcases of insects. The caterers provide for the labourers. Each one takes his own portion; there is no dispute, no fighting. The republic grows daily more numerous, living in profound peace. Every individual, as soon as he has acquired sufficient strength, flies away to the fields. They then become a gang of banditti; they pillage our wall-trees, break into our fruit before its maturity, dart with the fierceness of hawks upon our bees, cut their throats to possess themselves of their honey, plunder and lay waste their commonwealth, riot on the fruits of their labour, and oblige them to remove. During the period of plenty, the wasps bring all the booty to the nest, and share it amongst them. There is nothing then goes forwards but feasting, rioting, and good-fellowship; but concord cannot be lasting among robbers. Towards the month of October provisions begin to run short; when this lively, this amicable young brood is fired with a kind of rage, and the nest is now nothing but a scene of horror. The neuters and males tear from their cradles the eggs, the larvæ, the chrysalids, and the new-born insects, without showing mercy to any. They next fight one against another, though their duels seldom proceed to death as those of the bees. The males alone are destitute of stings. The hopes of the state, the solicitude for posterity, the love of their native

place, no longer exist; and the whole commonwealth is overturned to the very foundation. Frosts and rains throw the citizens into a state of languor. They almost all perish, luckily for us and our bees. Some few females escape the disasters of intestine war and the severity of winter, which in the ensuing spring become founders of new republics. One robber is sometimes useful in bringing another to punishment. Some butchers hang up before their shop a calf's liver or any other tender meat. The wasps come in quest of this delicate food; and, fond of enjoying it to themselves, they pursue the blue-bottle flies, from whose eggs are produced the maggots that spoil meat: and this is the only advantage we can reap from wasps.

3. The aerial wasps are a very small species; nor is their society numerous. Their history, as well as their manners, are the same as those of the common wasp; but their buildings are on a different construction. Their nest is fastened to the branch of a tree with a kind of a band, and is in figure from the size of an orange down to that of an egg. Wood reduced to paper is the material part of it, which, if it were of a ruddy colour, might be taken for a large opening rofe. It is covered over with a varnish impenetrable by water. One of those nests was neither mollified nor impaired by that element.—There are 25 other species.

VIRGULA DIVINA, or *Baculus divinatory*, &c. a forked branch, in the form of a Y, cut off an hazel-stick, by means whereof people have pretended to discover mines, springs, &c. under ground. The method of using it is thus: The person who bears it, walking very slowly over the places where he suspects mines or springs may be, the effluvia exhaling from the metals, or vapour from the water, impregnating the wood, makes it dip or incline, which is the sign of a discovery.

Some dispute the matter of fact, and deny it to be possible. Others, convinced by the great number of experiments alleged in its behalf, look out for the natural causes thereof: The corpulcels, say those authors, rising from the springs or minerals, entering the rod, determine it to bow down, in order to render it parallel to the vertical lines which the effluvia describe in their rise.

The famous Father Kircher, in his *Mundus Subterraneus*, in which many interesting particulars are found concerning mines, derides these practices, and denies, from his own experience, the truth of the assertions concerning them. He seems, however, to have some faith in sympathies, and proposes even new divining wands of his own invention; the effects of which, though more dependent on physical causes, are not, however, more certain. He believes, for instance, that a wand, one end of which should be made of sal gem, and the other of wood, being suspended and balanced above a mine of salt, would be inclined towards the ground; and he supports his opinion by an experiment. This experiment consists in evaporating over the fire a solution of sal gem below the wand, which is by this means really made to incline. We need not be deeply learned in chemistry to discover, that the wand would have inclined in the same manner if Father Kircher had evaporated pure water instead of a solution of sal gem; because the water would have equally well attached itself to the saline end of the wand; consequently this experiment proves nothing.

The same author proposes also to discover mines of

mercury by employing a wand, one end of which is made of gold, and the other of wood, in hopes that the emanations of the mercury would attach themselves to the gold rather than to the wood, and would make it incline downwards. But this effect certainly cannot be produced unless the mercury was evaporating; for which purpose two conditions are necessary: 1. The mercury must be in a native metallic state, and not mineralised, as it is in cinnabar; and, 2. it must also be exposed to the heat of some subterranean fire, by which it is volatilised and sublimed, the ordinary heat of the earth being far too little for this purpose. This second physical or chemical divining wand proposed by Father Kircher is therefore no better than the former; and probably the same judgment may be passed upon all other wands made upon the same principles and in imitation of these. Lastly, the same author positively affirms, that he hung and balanced a wand, one half of which was made of alder-tree, and the other half of some wood that has no sympathy with water, over a subterranean water, and that he observed the end of the wand incline towards the earth.

VITEX, the *AGNUS CASTUS*, or *Chaste Tree*; a genus of the angiospermia order, belonging to the dynamia class of plants. There are three species; of which the most remarkable is the *agnus castus*, or common chaste tree. This grows naturally in Sicily near Naples, by the sides of rivers, and in the Archipelago in moist places: it has a shrubby stalk 10 or 12 feet high, sending out branches opposite the whole length, which are angular, pliable, and have a greyish bark, garnished with leaves for the most part placed opposite, composed of five, six, or seven lobes, which unite at the footstalk, and spread out like the fingers of a hand, ending in blunt points, of a dark green on their upper side, but hoary on their under. The flowers are produced in spikes at the extremity of the branches, from seven to fifteen inches long, disposed in whorls round the stalks, with intervals between each whorl: they are of the lip-kind; the two lips are each cut into three segments, the middle being larger than the two sides; in some plants white, and in others blue; these are generally late before they appear; so that in bad seasons they do not open fair. The flowers have an agreeable odour, and make a good appearance in autumn, when the flowers of most other shrubs are gone; for, in warm mild seasons, these shrubs are in full flower in the middle of October.

This sort is pretty common in many English gardens, where it has been long an inhabitant, but was not much propagated till of late years. It is very hardy; and may be propagated by planting the cuttings early in the spring, before they shoot.

VITRIFICATION, the production of glass, one of the most curious and most important operations in chemistry. See GLASS, (*Encycl.*)

The hardness, beauty, and perfect transparency, of glass render it very extensively useful in ordinary life, in natural philosophy, in chemistry, and in many arts. Almost any form may be given to glass, and all kinds of vessels and utensils may be formed of it, which are capable of resisting the most powerful corrosives and solvents. Glass is capable of receiving and preserving the finest polish. Its properties of transmitting and refracting the rays of light, and of reflecting these rays when one of its surfaces is covered with a metallic coat, render it very useful for constructing mirrors, telescopes,

microscopes, and all kinds of optical glasses; for collecting, separating, and decomposing the rays of light; and for exhibiting many wonderful catoptrical and dioptrical appearances and experiments. If to these admirable properties we add that of imitating the many brilliant precious stones, opaque or transparent, we shall easily be convinced that perfect glass is one of the most beautiful and excellent productions of human industry.

Perfect glass, or the most beautiful facitious crystal, is perfectly similar in appearance to the whitest and most transparent natural vitrifiable stones. The only sensible difference between these natural and artificial productions is, that the latter are much less hard and more fusible than natural crystal or any other vitrifiable stone. In fact, pure glass or artificial crystal is essentially of the same nature as vitrifiable stones; or we may rather say, that it is vitrifiable earth itself rendered more fusible only by certain additions, as we shall soon show.

The most simple and elementary of all earths, called by chemists *vitrifiable earth*, forms the hardest and most transparent of all natural bodies when its ingredient parts are united together in a due state of aggregation: but the parts of vitrifiable earth cannot form this aggregation, unless they have been previously so much separated from each other that they possess a mobility, which enables them to unite together according to their natural tendency: the ingredient parts of elementary earth may acquire this mobility by two methods; namely, by the interposition of the parts of water or of those of fire.

Almost all the vitrifiable stones that we know, as diamonds, rock-crystal, and other hard transparent stones, appear to have been once dispersed in infinitely small molecules through much water, from which they have afterwards been deposited, and then have united together and formed the very hard transparent masses which we now see. Possibly some of these stones may have been formed by fire, and by a true fusion. Of these two ways, that of the division and elaboration by water cannot be practised by human art, on account of the many ages required for the operation.

By the second method, namely, fusion, the time required for which is better adapted to the shortness of our lives, we certainly might, with a sufficient degree of heat, melt vitrifiable earth, and all other kinds of earths; since these, when sufficiently purified, are reduced to the nature of vitrifiable earth; and we might convert these earths into masses of crystal, or of hard transparent stones, as perfect as the natural precious stones. In a word, nothing but a heat sufficiently intense is required to melt any earthy matter, and to convert it into a diamond as brilliant and as hard as the most perfect natural diamonds: but here a great, and hitherto unsurmountable, difficulty occurs, namely, to produce a heat sufficiently intense to melt the most pure and simple vitrifiable earth; for the most violent heat that art has ever produced is insufficient to melt even many of the common impure earths and stones; and is therefore much less capable of melting that earth, which, because it is the simplest and purest, is also the most infusible of all natural bodies.

Hence we conclude, that although we know by what means the parts of the purest earthy principle may be so united as to form bodies similar to the natural precious stones, yet we cannot possibly put these

means

means in execution: but if we cannot artificially produce solid masses of pure earth exactly similar in all their properties to the natural precious stones, we can however very well imitate these beautiful natural productions, not in their hardness and unfusibility, but in their transparency and lustre; that is, in their most obvious and striking qualities, by means of compositions of glass or factitious crystal. The solution of this problem is founded on the following principles.

First, pure and elementary earth, which makes the principal basis of all vitrifications, and therefore called *vitrifiable earth*, is indeed unfusible with regard to us: but we know, that certain very fusible substances are capable of uniting intimately with this earth, and of communicating to it some of their fusibility; so that by their means we may reduce it to a perfect fusion.

Secondly, the substances capable of acting upon the earthy principle are the inflammable principle or phlogiston, and several saline matters: but we may remark, that as these substances do only act as fluxes by uniting intimately with the vitrifiable earth, and while they themselves make part of the glass; and also, as the integrant parts of these fluxes are not capable of forming either with each other, or with the parts of vitrifiable earth, so strong an adhesion as that which can be formed between the parts of the pure vitrifiable earth; it follows, that all factitious crystal must be much less hard than natural crystals or other hard stones, since these contain only pure vitrifiable earth.

Thirdly, in consequence of the principle, that all compound bodies partake of the properties of their component parts, factitious crystals ought to partake so much more of the properties of inflammable and saline matters, and ought to be removed so much more from those of pure vitrifiable stones, as they contain a larger quantity of those matters. Accordingly we find, that the smaller quantity of flux that is contained in glass, the greater hardness, lustre, and resemblance to natural stones it has, provided the fusion has been complete. Thus glass is so much more perfect, as it possesses more of the properties of vitrifiable earth.

These principles, which are incontestable, being once understood, are easily applicable to the art of making glass; since, if we could produce a fire sufficiently intense, and had furnaces and vessels capable of sustaining it, we should make glass equal to the precious stones: it is therefore evident, that the most important object in vitrification, is to have furnaces capable of producing the greatest heat, and pots or crucibles capable of resisting, during a long time, this heat, and also the action of the vitrescent matter that they contain. These pots, as has been elsewhere observed, ought to be made entirely of the most refractory and purest clay, well washed and cleansed from all sandy, ferruginous, and pyritous matters, and mixed with a certain proportion of the same clay baked, and pounded not very finely. The quantity of baked clay that ought to be mixed with the crude clay, to prevent the pots from cracking, when dried or when exposed to violent heat, is not absolutely determined, but varies in different glass-houses, according as the crude clay employed be more or less fat, as it is called.

The ovens and furnaces are different, according to the quantity of materials to be vitrified. See the article *GLASS*, (*Encycl.*) In large works, wood or fossil coal are used; and the furnaces are so constructed that the flame of the fuel circulates and burns within very

intensely. As these furnaces vary much in different countries and glass-houses, and as a description would not be very intelligible without figures, we shall refer the reader to other works in which these several furnaces are described and represented; particularly to the French edition of *Neri's Art of making Glass*, with Notes by Merret and by Kunckel; and to an excellent Memoir by Dr D'Antic of Paris. We shall here say only in general, that these furnaces are placed under large and lofty buildings called *halls*; that they are covered with a vaulted roof; and that they have no chimney, but only lateral openings, through which the melted glass is drawn from the pots. Under these openings is built a kind of platform or banquette, on which the pots containing the glass stand, one of which is opposite to each opening. In the middle of the furnace, below the banquette, is a space, across which iron bars are laid. In this space, which communicates with a large cavity below called the *ash-hole*, the fuel is placed. In these furnaces, which have not any chimney, as we have said, the fire is nevertheless very intense. This intense heat is occasioned by the great capacity of the furnace, by means of which a strong draught of air passes continually from the ash-hole: besides, the flame being vividly agitated by air, and not being drawn out of the furnace by any chimney, circulates in every direction within the furnace, and produces a very violent heat. Most glass-house furnaces have also hollow towers that communicate with the cavity of the furnace, and which therefore increase the capacity of the whole. In these the heat is not nearly so intense as in the furnace. They are employed to contain the frit, or the pieces of manufactured glass that are to be annealed. Such is the general disposition of the furnaces of glass-houses.

Next to the good condition of the pots and furnaces, the most important and essential matter is the consideration of the kinds and proportion of the fluxes. Of these we may observe two kinds, namely, the inflammable and the saline. As we cannot obtain the pure inflammable principle, we must, when we intend that it should enter into the composition of glass, choose for this purpose some of the earthy substances with which it is found naturally combined; and these are particularly metallic earths, which are best adapted for conveying phlogiston into vitreous compositions: but all these earths are not equally fit for this purpose. All metals are composed of an earthy matter intimately combined with a sufficient quantity of the inflammable principle to be very fusible, and at the same time very opaque. Some of these metals, namely, those called *perfect*, are unalterable by fire, and cannot be entirely, or even partly, deprived of phlogiston: but as every metallic substance is incapable of uniting with earthy matters while it retains its metallic state, therefore no perfect metal can be vitrified. The case is different with those metallic substances, the phlogiston of which may be burnt, or otherwise destroyed. The earths or calxes of most, perhaps of all combustible metals, when not perfectly deprived of all their phlogiston, are capable of being reduced to a vitreous state, by means of their remaining inflammable principle. As they are not then in a metallic state, they can facilitate the fusion of vitrifiable earths, may contract with these an intimate union, and reduce them to a state of perfect vitrification: but these phlogificated calxes of imperfect metals promote vitrification more or less, ac-

Chem.
Dist.

Vitrification

cording to their particular natures. Some of these, as, for instance, tin, cannot be without great difficulty brought to that precise degree of calcination that is necessary to vitrification; because the heat required for this purpose deprives them of all their phlogiston, and renders them in a high degree refractory. Others, in whatever manner they be calcined, either retain too little phlogiston to be sufficiently fusible, although they still retain enough to give them colour; or if they be not calcined so much as to lose their fusibility, they cannot be melted but into opaque masses, so nearly in a metallic state that they cannot be united intimately with vitrifiable earths. Such, especially, are the earths of iron and of copper.

Of all metallic earths, that of lead is fittest for vitrification. This metal, which contains a large portion of phlogiston, is quickly deprived of so much of it, that it loses its metallic state, and is easily melted into a transparent vitreous mass; but it has, at the same time, this remarkable property, that when once it has lost as much phlogiston as is necessary to dispose it to vitrification, its calx strongly retains as much of it as is necessary to give to its greatest degree of vitrescibility; and that it may be sooner dissipated into vapours by the continued action of a very intense fire, than it can be changed into an earth totally dephlogisticated, and consequently refractory, like the calxes of tin and of regulus of antimony. Besides, the fusible earth of lead is one of these that retain the least colour. All these qualities render it preferable to any other metallic earth for the purposes of vitrification. The earth of bismuth, which in the above-mentioned properties resembles the earth of lead, may probably be employed with equal success; but as the calxes of lead are much more common than those of bismuth, the use of this semi-metal is not known to manufacturers of glass.

In whatever manner the calx of lead has been prepared, provided it be really in a calcined and not in a metallic state, it may be used in vitrification. Accordingly, the grey calx, or ashes of lead, massicot, red-lead, litharge, ceruss, and all the precipitates of lead, separated from acids by unmetallic intermediate substances, being mixed with sand or any other vitrifiable stone, and exposed to a sufficient degree of fire, do always promote the fusion of these matters, and form with them glasses more or less hard and transparent, according to the strength of the fire and the proportion of the ingredients.

The earth of lead constantly retains, as we have said, enough of the inflammable principle to preserve its fusibility. When it is exposed singly to the fire, it vitrifies with a very moderate heat. It has more phlogiston than is requisite for its vitrification. The fusibility, fluidity, and activity of this glass of lead, when pure, are so great, that it cannot be contained in any crucible, all which it easily pervades; therefore pure glass of lead is never made. But as the calx of lead has more phlogiston than is required for its own vitrification, it may divide this excess of inflammable principle with any unmetallic earths with which it is mixed, and thus may produce their fusion and perfect vitrification. The glasses formed by a mixture of calx of lead with unmetallic earths, have more consistence, hardness, and less fusibility, than pure glass of lead. The proportions of calx of lead and of sand employed in these kinds of glass are from one part to two

of calx of lead, to one of sand or of ground flints.

We may observe upon the subject of glasses that contain no other flux than phlogiston or metallic earths, of lead, or of any other metal, that none of them are perfectly white, but are all more or less coloured; because phlogiston is, as chemists know, the principle of colours. Secondly, these glasses have a greater density or specific gravity than any natural crystalline stone, all metallic earths being heavier than any that are not metallic.

Thirdly, metallic glasses are generally somewhat less brittle, are less liable to be broken by the alterations of heat and cold, and have more of a certain smoothness, or, as it were, unctuousity, not easily to be described, than glasses made altogether of unmetallic earths. These properties can only be attributed to the inflammable principle, a pretty considerable quantity of which is united with them. As these latter qualities of glass are valuable, a certain quantity of calx of lead generally enters into the composition of most fine glasses, which are distinguished from ordinary glass by the name *crystal-glass*.

From what we have said concerning the properties of metallic earths in vitrification, we may perceive, that the more calx of lead, or other metallic earth, enters into the composition of any glass, the more fusible, soft, coloured, and dense this glass is; and reciprocally. The colours given to glass by calxes of lead are shades of yellow.

Saline substances are the second kind of fluxes used in vitrification: but all these substances are not equally fit for this purpose; not that they are not all very fusible, but for several reasons hereafter to be mentioned.

First, neither the pure and disengaged acids, nor volatile alkalis, nor ammoniacal salts, can be employed as fluxes in vitrification; because none of these saline matters is sufficiently fixed. Their volatility is so great, that they may be totally dissipated by fire before they could act in any degree upon vitrifiable earth.

Secondly, none of the neutral salts with basis of fixed alkali, containing either vitriolic acid, or marine acid, can be employed as fluxes in vitrification. This proceeds, not from their want of fusibility, or of the necessary degree of fixity, but from the union of the acid and the alkali; which is so strong that they cannot act with sufficient force upon other substances, and particularly upon vitrifiable earth. The saline matters fit for vitrification are, fixed alkalis, vegetable and mineral; niter with basis of fixed alkali; sedative salt, and borax; fusible salt of urine, or rather phosphoric acid.

Of all saline matters, fixed alkalis, vegetable and mineral, are most frequently used in vitrification. These alkalis are fusible with a moderate heat; they are so fixed that they can resist during a sufficient time the heat of ordinary vitrifications; and they act powerfully upon flints, sands, and other vitrifiable stones. The proportion of alkali to sand, in order to make good glass, is, from one to two parts of the former ingredient, and two parts of the latter.

Nitre produces in vitrification nearly the same effects as fixed alkalis, although it be a neutral salt; the alkali and acid of which are united together nearly as they are in common salt, which however does not produce in vitrification similar effects. The remarkable difference in this respect betwixt these two salts, and

Chem. Dist.

Chem. Dist.

Vitrification

betwixt the nitre and the vitriolic salts, must be attributed to the great affinity of nitrous acid to the inflammable principle; which affinity is so strong, that when nitre is exposed to fire in vessels not perfectly close, the acid quits its alkaline basis to unite with the phlogiston of combustible matters, even though these be not sensibly in contact with it. Hence nitre exposed during a certain time to the action of a strong fire, is gradually alkalinised, and then becomes capable of dissolving very effectually vitrifiable earth. This alkalinisation is produced so much more easily in most vitrifications, that the ingredients employed generally contain some inflammable matter. Common salt cannot be alkalinised in this manner, because it cannot be decomposed by the contact of inflammable bodies, and therefore is not used in vitrifications: but as vitriolic acid has a strong affinity with phlogiston, we might be inclined to think, that vitriolic salts with basis of fixed alkali, which also are never used in vitrification, might perhaps be employed along with sand or other vitrifiable matters containing a larger proportion of phlogiston than the ingredients now commonly used do.

Fixed alkalis or nitre cannot be formed into transparent glass by being melted singly; because these salts contain too little of the earthy principle; for they form true glasses when they are mixed with a sufficient quantity of this principle, as with sands and other earthy matters: but borax, sedative salt, and the fusible salt of urine, may be melted without any earthy addition into transparent vitreous masses: and hence we may conclude, that these salts contain a larger portion of the earthy principle than nitre or fixed alkali. They nevertheless very powerfully promote the vitrification of other substances. These salts are not employed in the manufacture of large quantities of glass, because they are too dear. Borax is sometimes used for making small quantities of some particular kinds of fine glass.

Arsenic may be enumerated among vitrifying fluxes, as it is fusible and vitrescible singly, and is also capable of promoting the fusion of vitrifiable earths; for which purpose it is frequently employed as an ingredient in vitreous compositions. As arsenic partakes both of the metallic and saline properties, it probably acts in vitrification both as a salt and as a metallic earth. The quantity therefore of arsenic necessary to promote vitrification, is intermediate betwixt the quantities of calx of lead and of saline substances that are necessary for that purpose. But we must observe, that as arsenic is very volatile, a great part of it escapes in vapours upon the first application of heat, and that the quantity remaining is always uncertain. Arsenic cannot well be employed as the sole flux for vitrifiable earth. When we intend that a certain quantity of this matter should remain in the composition of a glass, one of the best methods that can be used for this purpose, is at the same time to add nitre to the ingredients of this glass; because the arsenic uniting with the alkaline basis of the nitre forms the neutral arsenical salt in which the arsenic is considerably fixed. But as this neutral arsenical salt is easily decomposed by contact of phlogiston, therefore no calx of lead or other substance containing the inflammable principle ought to be mixed with arsenic in the composition of glass. It has been found by experiment, that this neutral arsenical salt is very difficultly manageable in vitrifications, not only for the reason now given, but also from the property it has of powerfully corroding and pervading crucibles and pots.

In many mixtures, it quitted the vitrifiable earth with which it was mixed, and acted upon the crucible, which it penetrated and dissolved. These experiments seem to show, that arsenic has a greater affinity with clay than with vitrifiable earths.

From Mr Pott's experiments, chemists know, that vitrifiable, calcareous, and argillaceous earths, each of which are singly infusible, do reciprocally promote the fusion of each other, when mixed together nearly in equal proportions, and exposed to a very violent heat; and that from these mixtures matters perfectly vitrified are formed. But as we do not know the cause of this singular fusibility, we cannot determine whether it is produced by a phlogistic or by a saline substance, or perhaps by both.

Glasses that contain no other fluxing ingredient than phlogistic matters or metallic earths, partake of the properties of these metallic earths; and also glasses that contain only saline fluxes, partake of the properties of salts. The latter, or saline glasses, when pure and well proportioned, are less heavy, less dense, harder, whiter, more brilliant, more brittle, than the glasses containing calx of lead: and glasses containing both saline and metallic fluxes do also partake of the properties of both these substances. In general, glasses too saline are soft, and easily susceptible of alteration by the action of air and water; especially those in which alkalis prevail: which latter glasses are also liable to be attacked by acids, as we evidently see from the properties of the vitrified matter that is made with an excess of alkali, for the preparation of liquor of flints. Glasses containing too much borax and arsenic, although at first very beautiful, do quickly tarnish and become opaque when exposed to air.

From what we have said concerning the properties of fluxes, phlogistic or saline, we may know how to adjust the proportions of these to the sand or powdered flints for the various kinds of glass. Thus, if we require a glass that is dense, fusible, and not saline, one part and a half of red-lead or litharge may be mixed with one part of sand, and fused together. If equal parts of sand and of calx of lead be employed, a glass somewhat less dense and harder will be produced.

If a glass be required of very little density, only saline fluxes must be employed. A glass of this kind may be composed of six parts of salt of tartar, or of potash, or of purified soda, mixed with eight parts of sand or of flints; or of four parts of any of the above-mentioned alkalis, mixed with two parts of nitre or of borax, and eight parts of vitrifiable earth. These glasses must be left long in the fire, for the reasons hereafter to be mentioned.

When a crystal-glass is required which shall be of an intermediate quality betwixt the metallic and saline glasses, it may be made from a mixture of one part of the above-mentioned salts, one part of calx of lead, and two parts of sand or other vitrifiable earth. By varying the proportions of these ingredients, many different kinds of glasses may be produced, each of which may be good, if the quantity of each of the fluxes employed be proportionable to its vitrifying power. Several good receipts for glass and facitious crystal may be found in Neri's Art of Making Glass, with Notes by Merret and Kunckel; to which work we refer for many interesting particulars. See also the article GLASS, (Encycl.) We shall however observe, that the proportions of the fluxes necessary to produce any required kind

Chem.
Dist.

kind of glass cannot be precisely ascertained, for the following reasons.

First, the sands, flints, and other stones commonly employed for making of glass, are not all equally fusible. Thus the quartzose sand obtained by washing an earth found near Nevers, known to manufacturers of glass and of pottery by the name of *sand of Nevers*, may be almost entirely melted when exposed to a good vitrifying heat; and by a moderate heat its grains may be considerably rounded. There are some other hard stones, which in a violent fire are still more fusible, and convertible into an almost transparent glass without addition. The fusibility of these vitrescible stones is caused by some unknown heterogeneous matter united with them. These fusible sands and stones require a much less quantity of flux to promote their vitrification than other sands or vitrifiable stones which are much purer, and therefore more refractory.

Secondly, although the phlogistic and saline matters employed as fluxes in vitrification are sufficiently fixed to support the degree of fire necessary for the fusion of glass, they are nevertheless far from being so fixed as vitrifiable earth. The fire necessary for the perfect fusion of glass, is even sufficient to evaporate them entirely. Accordingly, in glass-houses where the pots are uncovered, a vapour or smoke continually rises from their surface, which is nothing else than the saline and phlogistic fluxes in a state of continual exhalation. Hence the longer glass remains melted in the fire, the harder and more difficultly fusible it becomes, and the more it partakes of the properties of pure vitrifiable earth. Accordingly, even when a very hard glass is required, such a quantity of flux ought to be added as shall at first promote a perfect fusion; and this fusion ought to be continued a long time till a considerable quantity of the flux is gradually dissipated, and till the glass has acquired the requisite degree of hardness, provided that the fire be sufficiently strong to maintain the fusion notwithstanding the loss of flux. From these observations it appears, that we cannot precisely ascertain the proportion of flux to vitrifiable earth, unless we knew the fusibility of the sand to be employed, and the degree of heat which can be excited in the furnace.

The saline fluxes, and especially the fixed alkalis employed in vitrification, are generally rendered impure by a mixture of several heterogeneous matters, and especially by neutral salts not vitrifiable, and by a certain quantity of inflammable principle. In manufactories of bottles and other common glass, the alkalis employed are not previously purified, but are even mixed with the earth of the ashes of the burnt plants, which earth is also much disposed to vitrification. Accordingly, to make glass of this kind, sand is mixed with common wood ashes, sometimes even with those which have been lixiviated, together with some unpurified potash, soda, or kelp; and from this mixture a brown, dusky, not very transparent glass is produced, which is preferred in common sale for wine bottles to clearer and more transparent glass. But when a fine, white, and very transparent glass is required, the alkali must be perfectly purified from all heterogeneous matter, by lixiviation and calcination.

As a too large quantity of the inflammable principle is the chief cause of the colours and of the opacity of glass, when a perfectly colourless and transparent glass is required, not only the alkalis must be deprived of all their superabundant phlogiston, but also the sands

or flints employed must be purified from any of this principle which they may contain. The method used for this purpose is by mixing together the due proportions of sands and salts, by exposing this mixture during a considerable time to a red heat, not intense enough to melt it. By this calcination, the phlogiston of these matters is burnt and dissipated, all colour is destroyed, and the glass produced is also more clear and brilliant. This first mixture of materials of glass, when calcined, is called the *fritt*; and this fritt is used in large manufactories not only for the finer glass, but also for the common brown glass; not with an intention to render this latter kind of glass colourless, but because, during this calcination, the salts and earth begin to act upon each other, and to incorporate in a certain degree; by which a great part of the effervescence and swelling occasioned by the reaction of these matters, which happen when they are at once exposed to a melting heat, are avoided. Accordingly, when matters not previously fritted are employed in small experiments, the heat must be applied gradually; otherwise they so swell, that frequently the greatest part of the mixture runs over the crucible.

The due degree of heat is an essential point in making of glass; it ought not only to be very strong, but also maintained during a long time. In great manufactories, the glass is kept fused during ten or twelve hours before it is taken out of the pots. Accordingly their glass is always more perfect than that which is hastily made in small quantity in two or three hours. Good glass, although kept in fusion in a very great heat, is not perfectly liquid. It is always somewhat thick, and when taken from the crucible, it may be drawn out into fine wire or threads; which shows that it has a certain consistence and a very sensible tenacity when it is red-hot. It is not transparent while it remains red-hot, not even when it has become perfectly hard. Another remarkable circumstance is, that glass which is so brittle when it is cold and transparent, is very ductile when it is so heated as to be opaque. We might be induced to believe, that the disengaged fire with which the glass is filled when it is red-hot, produces upon it the same effect that phlogiston or combined fire produces upon metals. The ductility of red-hot glass is very useful; for by its means all imaginable shapes may be given to glass, and numberless vessels and utensils may be easily formed of it.

As soon as glass-vessels have received their intended form, they must be cooled very gradually, otherwise they would have no solidity, and would be of little use, as they would be liable to be broken by the smallest stroke, or by a slight change of heat and cold. This inconvenience is prevented in glass-houses by carrying the glass vessels as soon as they are formed, and while yet red-hot, into an oven too little heated to destroy their form. But in which they may be very gradually cooled. This is called *annealing the glass*.

Notwithstanding all the care taken in the manufactories of the finer kinds of glass, as crystal-glass and plate-glass, to make them perfectly good, they are nevertheless seldom found quite free from faults. The principal faults in glass are, colours, bubbles, and veins. The colours which generally hurt glass, especially that kind which contains saline fluxes, are shades of green, olive, and blue. These colours are destroyed by manganese; which being added in small quantities, clears the glass, and is therefore sometimes called by artists

Chem.
Diâ.

Chem.
Diâ.

the soap of glass. This effect of manganese cannot easily be explained, for it has the property of tinging glasses with a purple colour. Mr Montamy, in his *Traité des Couleurs pour la Peinture en Email*, has a very fine and ingenious thought upon this subject; which is, that the manganese destroys the above-mentioned colours, by adding to these a purple tinge, and by the mixture producing a blackish brown colour; and that as blackness is caused merely by an absorption of the rays of light, therefore the blackish tinge given to the glass by the above mixture of colours, prevents the reflection of so many rays, and thus renders the glass less coloured than before. The causes of the bubbles and of the veins in all glass, even when most carefully prepared, and the methods of preventing these faults, are not sufficiently known.

We shall observe, in concluding this article, that several causes lessen or entirely prevent the transparency of glass, which is one of its most necessary qualities. As we cannot melt vitrifiable earth into transparent masses but by means of fluxes, and a sufficiently strong and long-continued heat, therefore when the vitreous mixture contains too little flux, or is exposed to too little heat, some parts of the vitrifiable earth cannot be entirely fused, and therefore injure more or less, according to their quantity, the transparency of the glass. The same fault may be perceived in glass, when it contains some earthy matter not susceptible of the action of fluxes, as vitrifiable earth is; such as, for instance, most metallic earths that are too much deplogified, particularly the earth of tin. Accordingly, these earths are employed to make opaque or semi-transparent glasses, as enamels, artificial opals, and other such stones. Another remark may be made concerning the transparency of some kinds of glass, that it is destructible by a too long exposure to violent heat. As all fluxes, phlogistic or saline, are much less fixed than vitrifiable earth, and as some fluxes are less fixed than others, or less capable of becoming fixed by being mixed with vitrifiable earth; the cause therefore of the loss of transparency which some glasses suffer by a too violent fire is, that a part of their flux is dissipated, so that these glasses are decomposed, and that they contain so much earth that the flux is incapable of keeping them completely fused. It has been observed that glasses formed by a mixture of argillaceous and gypseous or calcareous earths, are more liable than any others to this loss of transparency.

UNIVERSE, (*Encycl.*) As space is in its own nature every way infinite, it gives us an idea of the infinity of the universe, which can therefore be only in part comprehended by us: and that part of the universe which we can have any notion of, is that which is the subject of our senses; and of this the eye presents us with an idea of a vast extended prospect, and the appearance of various sorts of bodies disseminated through the same.

The infinite abyss of space, which the Greeks call *to pan*, the Latins *inane*, and we the *universe*, does undoubtedly comprehend an infinity of systems of moving bodies round one very large central one, which the Romans called *sol*, and we the *sun*. This collection of bodies is therefore properly called the *solar system*, and sometimes the *mundane system*, from the Latin word *mundus* the "world."

That the universe contains as many solar systems or worlds as there are what we call fixed stars, seems

reasonable to infer from hence, that our sun, removed to the distance of a star, would appear just as a star does, and all the bodies moving about it would disappear entirely. Now the reason why they disappear is, because they are opaque bodies, and too small to be seen at so great a distance, without an intense degree of light; whereas theirs is the weakest that can be, as being first borrowed, and then reflected to the eye.

But the sun, by reason of his immense bulk and innate light, which is the strongest possible, will be visible at an immense distance; but the greater the distance, the less bright it will appear, and of a lesser magnitude: and therefore every star of every magnitude may probably be a sun like our own, informing a system of planets or moving bodies; each of which may be inhabited, like our earth, with various kinds of animals, and stored with vegetable and other substances.

We can perceive, says Mr Maclaurin, no bounds of the vast expanse in which natural causes operate; nor can we fix any border or termination of the universe; and we are equally at a loss to trace things to their elements, and to discover the limits which enclose the subdivisions of matter. The objects which we commonly call great, vanish when we contemplate the vast body of the earth. The terraqueous globe itself is soon lost in the solar system; being in some parts seen as a planet or distant star, and in great part of the system unknown, or visible only at rare times to vigilant observers, assisted perhaps with instruments like our telescopes. The sun itself dwindles into a star: Saturn's vast orbit, and the orbits of all the comets, crowd into a point when viewed from numberless places between the earth and the nearest fixed stars. Other suns illuminate other systems where our sun's rays are unperceived: but all these are also swallowed up in the vast expanse of the universe. Even all the systems of the stars that sparkle in the clearest sky, must possess a small corner only of that space over which such systems are dispersed. And after we have risen so high, and left all definite measures so far behind us, we find ourselves no nearer to a term or limit; for all this is nothing to what may be displayed in the infinite expanse, beyond the remotest stars that ever have been discovered.

In this view of the universe, an august idea arises in the mind, worthy of the infinite and wise Author of nature, who can never be supposed to have created so many glorious orbs, to answer so trifling a purpose as the twinkling to mortals by night now and then; besides that the far greatest part of the stars are never seen by us at all.

USNEA, in botany, a genus of mosses, wholly destitute of leaves, and composed only of long slender filaments or stalks, which are usually solid, rigid, and of a cylindric figure. The extremities, or other parts of these, are at times furnished with a sort of orbicular bodies, dry and destitute of use, but seeming to supply the place of flowers. These are hollow, in form of cups, but have no rim. The whole plants are fixed in the manner of mistletoe to the barks of trees. Micheli has given accounts of flowers and seeds in these plants; but Dillenius suspects the accuracy of this observation, and adds, that if there are such, they are too minute to be of any service in the general distinctions of the plants. See Plate CCCXX.

WAND,

W.

Wand,
Warburton.**WAND, DIVINING.** See *VIRGULA Divina* in this Appendix.

WARBURTON (William), bishop of Gloucester, a learned prelate, was born at Newark upon Trent, in the county of Nottingham, Dec. 24. 1698. His father was George Warburton, an attorney, and town-clerk of the place, in which this his eldest son received his birth and education. While at school, the bishop showed no indication of superior genius. His original designation was to the same profession as that of his father and grand-father; and he was accordingly placed clerk to an attorney, with whom he remained until he was qualified to engage in business upon his own account. He was then admitted to one of the courts at Westminster; and for some years continued the employment of an attorney and solicitor at the place of his birth. The success he met with as a man of business was probably not great. It was certainly insufficient to induce him to devote the rest of his life to it; and it is probable, that his want of encouragement might tempt him to turn his thoughts towards a profession in which his literary acquisitions would be more valuable, and in which he might more easily pursue the bent of his inclination. He appears to have brought from school more learning than was requisite for a practising lawyer. This might rather impede than forward his progress, as it has been generally observed, that an attention to literary concerns, and the bustle of an attorney's office, with only a moderate share of business, are wholly incompatible. It is therefore no wonder that he preferred retirement to noise, and relinquished what advantages he might expect from continuing to follow the law. It has been suggested by an ingenious writer, that he was for some time usher to a school. In the year 1724, his first work, consisting of translations from Cæsar, Pliny Claudian, and others, appeared under the title of "Miscellaneous Translations in Prose and Verse, from Roman Poets, Orators, and Historians," 12mo. It is dedicated to his early patron, Sir Robert Sutton, and seems to have laid the foundation of his first ecclesiastical preferment. At this period it is probable he had not abandoned his profession, though it is certain he did not attend to it much longer. About Christmas 1726 he came to London; and while there, was introduced to Theobald, Concanen, and others of Mr Pope's enemies, with whose conversation he was extremely pleased. In 1727, he published a work, entitled, "A Critical and Philosophical Enquiry into the Causes of Prodigious and Miracles, as related by Historians," &c. 12mo, and was also dedicated to Sir Robert Sutton. He was at this time in orders, and on the 25th of April 1728, had the honour to be in the king's list of Masters of Arts, created at Cambridge, on his majesty's visit to that university. In June, the same year, he was presented by Sir Robert Sutton to the rectory of Burnt Broughton, in the county of Lincoln; a living which he retained till his death, at which he spent a considerable part of his middle life in a studious retirement, devoted entirely to letters, and there planned, and in part executed, some of his most important works. Several years elapsed, after obtaining this preferment, before Mr Warburton appeared again in the world as

a writer. It was in this year 1736, that he may be said to have emerged from the obscurity of a private life into the notice of the world. The first publication which rendered him afterwards famous now appeared under the title of "The Alliance between Church and State; or, the Necessity and Equity of an Established Religion and a Test-law, demonstrated from the Essence and End of Civil Society, upon the fundamental Principles of the Law of Nature and Nations." At the end was announced the scheme of "The Divine Legation of Moses demonstrated on the Principles of a religious Deist, from the omission of the doctrine of a future state of rewards and punishments in the Jewish dispensation;" and met with a reception which neither the subject, nor the manner in which it was treated, seemed to authorize. It was, as the author afterwards observed, fallen upon in so outrageous and brutal a manner, as had been scarce pardonable, had it been "The Divine Legation of Mahomet."—It produced several answers, and so much abuse from the authors of "The Weekly Miscellany," that in less than two months he was constrained to defend himself, in "A Vindication of the Author of the Divine Legation of Moses, from the Aspersions of the Country Clergyman's Letter in the Weekly Miscellany of February 24, 1737-8," 8vo. Mr Warburton's extraordinary merit had now attracted the notice of the heir-apparent to the crown; in whose immediate service we find him in June 1738, when he published "Faith working by Charity to Christian Edification; a sermon preached at the last episcopal visitation for confirmation in the diocese of Lincoln; with a preface, showing the reasons of its publication, and a postscript, occasioned by some letters lately published in the Weekly Miscellany. By William Warburton, M. A. Chaplain to his Royal Highness the Prince of Wales." A second edition of "The Divine Legation" also appeared in November 1738. In March 1739, the world was in danger of being deprived of this extraordinary genius by an intermitting fever, which with some difficulty was relieved by a plentiful use of the bark. The "Essay on Man" had now been published some years; and it is universally supposed that the author had, in the composition of it, adopted the philosophy of Lord Bolingbroke, whom on this occasion he had followed as his guide, without understanding the tendency of his principles. In 1738, M. de Crousaz wrote some remarks on it, accusing the author of Spinozism and Naturalism; which falling into Mr Warburton's hands, he published a defence of the first epistle, and soon after of the remaining three, in seven letters, of which six were printed in 1739, and the seventh in June 1740, under the title of, "A Vindication of Mr Pope's Essay on Man, by the Author of the Divine Legation." The opinion which Mr Pope conceived of these defences, as well as of their author, will be best seen in his letters. In consequence, a firm friendship was established between them, which continued with undiminished fervour until the death of Mr Pope; who, during the remainder of his life, paid a deference and respect to his friend's judgment and abilities, which will be considered by many as almost bordering on servility. In 1741, the second volume of "The Divine

Legation" was published; as was also a second edition of the "Alliance between Church and State." Mr Pope's affection for Mr Warburton was of service to him in more respects than merely increasing his fame. He introduced and warmly recommended him to most of his friends, and amongst the rest to Ralph Allen, Esq. of Prior-Park, whose niece he some years afterwards married, and whose great fortune at length came to his only son. In 1742, Mr Warburton published "A Critical and Philosophical Commentary on Mr Pope's Essay on Man." In which is contained a Vindication of the said essay from the misrepresentations of M. de Resnel, the French translator, and of M. de Croufay, professor of philosophy and mathematics in the Academy of Lausanne, the commentator. It was at this period when Mr Warburton had the entire confidence of Mr Pope, that he advised him to complete the Dunciad, by changing the hero, and adding to it a fourth book. This was accordingly executed in 1742, and published early in 1743, 4to, with notes by our author; who, in consequence of it, received his share of the satire which Mr Cibber liberally bestowed on both Mr Pope and his annotator. In the latter end of the same year, he published complete editions of "The Essay on Man," and "The Essay on Criticism;" and, from the specimen which he there exhibited of his abilities, it may be presumed Mr Pope determined to commit the publication of those works which he should leave, to Mr Warburton's care. The publication of "The Dunciad" was the last service which our author rendered Mr Pope in his life-time. "The Divine Legation of Moses" having now been published some time, and various answers and objections to it having started up from different quarters, Mr Warburton, in 1744, turned his attention to these attacks on his favourite work; and defended himself in a manner which, if it did not prove him to be possessed of much humility or diffidence, at least demonstrated, that he knew how to wield the weapons of controversy with the hand of a master. His answers are couched in those high terms of confident superiority, which marked almost every performance that fell from his pen during the remainder of his life. At this important crisis, 1745, Mr Warburton printed three very excellent and seasonable sermons, 1. "A faithful Portrait of Popery, by which it is seen to be the reverse of Christianity, as it is the Destruction of Morality, Piety, and Civil Liberty. A Sermon preached at St James's Church, Westminster, Oâ. 1745, 8vo." 2. "A Sermon occasioned by the present unnatural Rebellion, &c. preached in Mr Allen's Chapel at Prior-Park, near Bath, Nov. 1745. and published at his request," 8vo. 3. "The nature of National Offences truly stated. A Sermon preached on the General Fast-day, Dec. 18. 1745," 8vo, 1746. Notwithstanding his great connections, his acknowledged abilities, and his established reputation, yet we do not find that he received any addition to the preferment given him in 1728 by Sir Robert Sutton (except the chaplainship to the Prince of Wales), until April 1746, when he was unanimously called by the Society of Lincoln's-Inn to be their preacher. In 1747 appeared his edition of Shakespeare, and his Preface to Clarissa; and in the same year he published, 1. "A Letter from an Author to a Member of Parliament, concerning Literary Property," 8vo. 2. "Preface to Mrs Cockburn's Remarks upon the Principles and

Reasonings of Dr Rutherford's Essay on the Nature and Obligations of Virtue," &c. 8vo. 3. "Preface to a Critical Inquiry into the Opinions and Practice of the ancient Philosophers, concerning the Nature of a Future State, and their Method of teaching by double Doctrine," (by Mr Towne,) 8vo, 1747, 2d edition. In 1748, a third edition of "The Alliance between Church and State; corrected and enlarged." In 1749, a very extraordinary attack was made on the moral character of Mr Pope, from a quarter where it could be the least expected. His "Guide, Philosopher, and Friend," Lord Bolingbroke, published a book which he had formerly lent Mr Pope in MS. The preface to this work, written by Mr Mallet, contained an accusation of Mr Pope's having clandestinely printed an edition of his Lordship's performance without his leave or knowledge. A defence of the poet soon after made its appearance; which was universally ascribed to Mr Warburton, and was afterwards owned by him. It was called, "A Letter to the Editor of the Letters on the Spirit of Patriotism, the Idea of a Patriot King, and the State of Parties, &c. occasioned by the Editor's Advertisement," &c. which soon afterwards produced an abusive pamphlet, under the title of "A Familiar Epistle to the most impudent Man living," 8vo; a performance, as hath been truly observed, couched in language bad enough to disgrace even galls and garrets. About this time the publication of Dr Middleton's Enquiry concerning the Miraculous Powers gave rise to a controversy, which was managed with great warmth and acerbity on both sides, and not much to the credit of either party. On this occasion Mr Warburton published an excellent performance, written with a degree of candour and temper, which, it is to be lamented, he did not always exercise. The title of it was, "Julian; or a Discourse concerning the Earthquake and Fiery Eruption which defeated that Emperor's attempt to rebuild the Temple at Jerusalem," 8vo, 1750. In 1751, he gave the public his edition of Mr Pope's works, with notes, in nine volumes 8vo; and in the same year printed "An Answer to a Letter to Dr Middleton, inserted in a pamphlet intitled, The Argument of the Divine Legation fairly stated," &c. 8vo, and "An Account of the prophecies of Arise Evans, the Welch prophet, in the last century;" the latter of which pieces afterwards subjected him to much ridicule. In 1753, Mr Warburton published the first volume of a Course of Sermons preached at Lincoln's Inn, intitled, "The Principles of Natural and Revealed Religion occasionally opened and explained;" and this, in the subsequent year, was followed by a second. After the public had been some time promised the appearance of Lord Bolingbroke's works, they were about this time printed. Many answers were soon published, but none with more acuteness, solidity, and sprightliness, than "A View of Lord Bolingbroke's Philosophy, in two Letters to a Friend, 1754;" the Third and Fourth Letters were published in 1753, with another edition of the two former; and in the same year a smaller edition of the whole; which, tho' it came into the world without a name, was universally ascribed to Mr Warburton, and afterwards publicly owned by him. To some copies of this is prefixed an excellent complimentary epistle from the President Montesquieu, dated May 26. 1754. At this advanced period of his life, that preferment which his a-

bilities might have claimed, and which had hitherto been withheld, seemed to be approaching towards him. In September 1754, he was appointed one of his Majesty's chaplains in ordinary, and in the next year was presented to a prebend in the cathedral of Durham, on the death of Dr Mangey. About the same time the degree of Doctor of Divinity was conferred on him by Dr Herring, then archbishop of Canterbury. In 1757, a pamphlet was published, called "Remarks on Mr David Hume's Essay on the Natural History of Religion;" which is said to have been composed of marginal observations made by Dr Warburton, on reading Mr Hume's book; and which gave so much offence to the author as to advert upon, that he thought it of importance enough to deserve particular mention in the short account of his life. On the 11th of October, in this year, our author was advanced to the deanry of Bristol; and at the latter end of 1758, received the honour so justly due to his merit, of being dignified with the mitre, and promoted to the vacant see of Gloucester. In 1762, he published "The Doctrine of Grace; or, the Office and Operations of the Holy Spirit vindicated from the Insults of Infidelity and the Abuses of Fanaticism," 2 vols, 12mo; and in the succeeding year drew upon himself much illiberal abuse from some writers of the popular party, on occasion of his complaint in the House of Lords, on the 15th of November 1763, against Mr Wilkes, for putting his name to certain notes on the infamous "Essay on Woman." In making his complaint, the bishop, after solemnly disavowing both the Poem and the Notes, avowed, that the former was worthy of the Devil; then, after a short pause, added, "No, I beg the Devil's pardon, for he is incapable of writing it." The year 1777 produced a third volume of his Sermons, dedicated to Lady Mansfield: and with this, and a single "Sermon preached at St Lawrence Jewry, on Thursday April 30. 1767, before his Royal Highness Edward duke of York, President, and the Governors of the London Hospital, &c." 4to, he closed his literary labours. His faculties continued unimpaired for some time after this period; and in 1769 he gave considerable assistance to Mr Ruffhead in his life of Mr Pope. He also transferred 500 l. to Lord Mansfield, Judge Wilmot, and Mr Charles Yorke, upon trust, to found a Lecture in the form of a course of Sermons; to prove the truth of Revealed Religion in general, and of the Christian in particular, from the completion of the prophecies in the Old and New Testament, which relate to the Christian Church, especially to the apostacy of Papal Rome. To this foundation we owe the admirable Introductory Lectures of bishop Hurd, and the well-adapted continuation of bishop Halifax and dean Bagot. It is a melancholy reflection, that a life spent in the constant pursuit of knowledge frequently terminates in the loss of those powers, the cultivation and improvement of which are attended to with too strict and unabated a degree of ardour. This was in some degree the misfortune of Dr Warburton. Like Swift, and the great duke of Marlborough, he gradually sunk into a situation in which it was a fatigue to him to enter into general conversation. There were, however, a few old and valuable friends in whose company, even to the last, his mental faculties were exerted in their wonted force; and at such times he would appear cheerful for several hours, and on the departure of his friends retreat as it were within himself. This me-

lancholy habit was aggravated by the loss of his only son, a very promising young gentleman, who died of a consumption but a short time before the bishop himself resigned to fate, in the 81st year of his age.

WATER-HEMLOCK, Common. This plant is very common in England. It is a well known fact in Sweden, that horses will eat it, and that it frequently proves fatal to them by inducing a palsy: this effect, nevertheless, is judged to be owing to an insect which inhabits in great plenty the stalks of this herb, and from this singular effect is called by Linnæus *curculio paraplecticus*, when in its perfect state, as the larva only exists in this vegetable. The same caterpillar is found in the water-parsnip also in England.

WATER Hemlock, Long leaved. Happily this plant is not very common in England: the roots are the most virulent vegetable poison that is indigenous here. Linnæus, in the *Flora Lapponica*, n° 103. gives a dreadful account of the havoc it made among the horned cattle in Lapland, where it is common in the meadows near the sea, and where these cattle will frequently eat it, upon being first turned to grass in the spring, though they afterwards refuse it: yet they will eat the roots at all times, which are the most virulent parts of the plant. Bishop Gunner and Gmelin both confirm these bad effects. It is yet doubtful whether horses are hurt by it; and certain that goats are delighted with it, and eat it without any subsequent ill effect: and the roots are collected by the Norwegian peasants as fodder for those animals.

WATSON (Robert), an elegant historian, was born at St Andrews, in Scotland, about the year 1730. He was the son of an apothecary of that place, who was also a brewer. Having gone through the usual course of languages and philosophy at the school and university of his native place, and also entered on the study of divinity, a desire of being acquainted with a larger circle of literature, and of improving himself in every branch of knowledge, carried him, first to the university of Glasgow, and afterwards to that of Edinburgh. The period of theological studies at the universities of Scotland is no less than six years: but during that period, young men of ingenious minds find sufficient leisure to carry on and advance the pursuits of general knowledge. Mr Watson pursued his studies with ardour. Few men ever studied more constantly. It was a rule with him to study eight hours every day; and this law he observed during the whole course of his life. An acquaintance with the polite writers of England, after the union of the two kingdoms, became general in Scotland; and in Watson's younger years, an emulation began to prevail of writing pure and elegant English. Mr Watson applied himself with great industry to the principles of philosophical or universal grammar; and by a combination of these, with the authority of the best English writers, formed a course of lectures on style or language. He proceeded to the study of rhetoric or eloquence; the principles of which he endeavoured to trace to the nature of the human mind. He delivered a course of lectures in Edinburgh on these subjects; and met with the countenance, approbation, and friendship of lord Kaimes, Mr Hume, with other men of genius and learning.

At this time he had become a preacher; and a vacancy having happened in one of the churches of St Andrews, he offered himself a candidate for that living, but was disappointed. Mr Henry Rymer, who then

then taught logic in St Salvador's College, was in a very infirm state of health, and entertained thoughts of retiring from the cares and emoluments of his office, to live upon his small salary or stipend. Mr Watson understanding this, purchased, for not a great sum of money, what, in familiar phraseology, may be called the good-will of Mr Rymer's place; and, with the consent of the other masters of St Salvador's, was appointed professor of logic. He obtained also a patent from the crown, constituting him professor of rhetoric and belles lettres. The study of logic, in St Andrews, as in most other places, was at this time confined to syllogisms, modes, and figures. Mr Watson, whose mind had been opened by conversation, and by reading the writings of the wits that had begun to flourish in the Scotch capital, prepared and read to his students a course of metaphysics and logics on the most enlarged and enlightened plan; in which he analyzed the powers of the mind, and entered deeply into the nature of the different species of evidence of truth or knowledge. By his history of Philip II. Dr Watson attained in his lifetime a considerable degree of celebrity; and his history of Philip III. published after his death, has added to his fame. Of this last performance, however, he has only completed the four first books; the two last were written by the editor of his manuscript, at the desire of the guardians of his children.

On the death of principal Tulideph, Dr Watson, through the earl of Kinnoull, was appointed his successor; in which station he lived only a few years. He married a lady of singular beauty and virtue, daughter to Mr Shaw, professor of divinity in St Mary's college, St Andrews. By this lady he had five daughters, who have lately obtained a small pension from government, through the active humanity of Mr Dundas then Lord Advocate for Scotland.

WEATHER, (*Encycl.*) Many have laboured with extreme diligence to explore the secret causes of the various changes of weather, and to foretell these alterations with certainty, but hitherto with no great success. Indeed, in this country at least, the alterations of the weather are so many, and frequently so sudden, that we can scarce suppose them to depend on any constant and regular cause. In the warm climates the weather is much more constant and uniform than with us; and even on the Continent in equal latitudes, it is less variable than here. Between the tropics, and probably for a considerable space northward and southward, the sun appears to be the principal agent in determining the weather. At one season of the year immense quantities of vapour are raised into the atmosphere, which, when the solar influence becomes less, are condensed into violent rains, and thus distinguish the year into the dry and rainy seasons. In those climates also the general course of the wind is evidently influenced by the sun, as Dr Halley has observed, (*See WIND, Encycl.*) Indeed at some times violent storms of wind, called *hurricanes*, whirlwinds, and storms of thunder and lightning, will occur: but of these the sun can only be accounted the remote cause; the immediate one being most probably the highly electrified state of the atmosphere. The inhabitants of those climates, especially the savages, who are continually exposed to the atmosphere, are able to foretell these tempests some time before. The signs which they observe, however, are in fact only the tempest beginning its operations in the atmosphere; and no

person whatever is able to foretell an hurricane or a storm of thunder a month, or even a week, before it comes. The reason of this is, that the sources of atmospheric electricity are not only invisible to us, but so variable in themselves, that though we knew them at one time, we have not the least security they that would continue the same even for a day. In various parts of this work it has been shown, that the sun communicates the electric fluid to the earth, and that this fluid must escape somewhere from the earth into the atmosphere in the very same quantity in which it is communicated. As the electric fluid, however, cannot easily diffuse itself in the atmosphere, an accumulation of it over any particular spot must soon take place; in which case that spot will cease to emit any more electric fluid. If then a new vent is opened, a current of electric matter may perhaps be directed from that place which emitted it before; and then the atmosphere, instead of receiving electricity from the earth, will communicate its superfluous quantity to it. In such a situation of the atmosphere, storms of thunder may readily take place; but where there is nearly an equal degree of electricity in the earth and atmosphere, an earthquake is most likely to ensue. (*See EARTHQUAKE, n° 39. art. 10. Encycl.*) Besides the mere accumulation of electricity in the atmosphere, there are other causes, such as severe frosts, which may detain the fluid in various parts of the earth at particular times; and thus be indirectly the cause of thunder, earthquakes, &c. in other places. This will easily show the difficulty, nay the impossibility, of predicting these storms; as the causes of them may be very remote from the place where they happen. An hurricane in Jamaica, for instance, may be occasioned by something in New Britain, or an earthquake in Portugal by something in Sweden or Norway.

In our own climate, nothing can be more variable and uncertain than the weather. Some have attempted to deduce its changes from the influence of the moon; but, though it cannot be doubted that the moon as well as the sun has some influence on our atmosphere, the changes in it are by far too many to be occasioned by any regular and permanent cause.—The wind has likewise been thought considerably to influence the weather: but excepting with regard to heat or cold, we cannot find that this is to be depended upon; not to mention that the wind itself makes part of the weather, and ought to have its cause explained as much as the rest. That alterations of the weather, however, do not depend immediately either on the sun, moon, or wind, appears from a circumstance mentioned by Mr Derham, viz. that “moles dig *before a thaw*.” This he ascribes to *warm vapours* which they feel in the earth; but whatever it is, we from thence learn, that the cause of this alteration lies not in the atmosphere, but in the earth itself, from whence it would seem to be communicated to the atmosphere.

But though it is probable that the action of the electric fluid in the earth is the cause of those sudden changes which are met with in almost all countries; yet the general determination of the weather, or what is called the *climate*, evidently depends on some settled and permanent cause. The cold of winter and heat of summer are plainly occasioned by the greater or less obliquity of the sun's rays at those seasons. To the sun also are we to ascribe those regular winds which, though most remarkable within the tropics, are yet in some degree to be met with even in our own country.

Thus, notwithstanding the excessive variableness of our climate, we may determine the general outline of the weather from evident causes. Thus in the months of January and February we may reasonably expect frost and snow, from the condensed and cold air in the northern regions pressing southward to those parts rarefied by the sun. In March we very often meet with the same, by reason of the weak influence of the sun at that time; but more frequently there are at that time storms of wind from various quarters, but frequently from the west or north. The reason of this is, that the air over the land begins to be rarefied; in consequence of which the denser air rushes in from that quarter where the passage is most free.—In April, the rarefaction of the air being greater, and considerable quantities of electric matter thus passing from the earth into it, the winds cease, or become more gentle, and rains commence. In the beginning of May the wind often blows very cold from the north, though the weather is more settled. Why this wind did not take place in April, seems not so easily accounted for; but most probably the difference of density between the northern and southern air was not then sufficient to allow of a strong current from any quarter. During the latter part of May and the whole of June, the weather is usually settled and clear; the sun gradually exerting his greatest influence. In July we have thunder and rain, for the reasons already given. The latter part of August and the whole of September are usually dry, with westerly winds, in consequence of the latter having prevailed in the conflict with the east wind. The

whole month of October, and great part of November, is usually rainy, on account of the interference of the west and north winds; and in the end of November, and throughout the month of December, frost and snow come on, though not with such certainty as in January.

This, in general, is the weather we may expect throughout the year; but by many accidental causes, not easily discoverable, it may be very much altered. Some of these causes we have endeavoured to point out; but, besides the reasons already given, it is not impossible that an alteration may take place in our atmosphere from causes entirely beyond it, and which exist only in the immense mass of ethereal fluid with which the universe is filled. Such causes, however, as they must be totally without the reach of our investigations, can never be assigned as the reason of any kind of weather; yet in some seasons there is such a general cold over a great part of the earth, that we must certainly imagine the cause to have been very high in the atmosphere. Of this the year 1782 furnishes us with a notable example. During the whole of that summer the sun appeared almost totally to have lost his influence. No vegetable, not even grass, came to perfection; and the harvest was scarce finished in the month of December. This was the case in Scotland, and it seems to have been similar all over Europe. The cause of this extraordinary cold, we cannot discover; but its effects were very obvious and dreadful. The electric fluid being confined over so large a space, broke out in the southern parts with fury; and Sicily and Calabria were almost entirely ruined by earthquakes. The earth now poured out such immense quantities of electric matter, that the atmosphere seemed scarce able to contain it. It therefore diffused itself along the lower regions all over Europe. Heat and almost perpetual thunder were the consequence: vegetation was excessively luxuriant; but the immoderate quantity of electricity having occasioned continual fogs which obscured the sun, fruits had not their proper flavour; nor was the crop altogether what might have been expected. The electric fluid, in the mean time, having fully saturated the lower part of the atmosphere, gradually ascended higher; but as the earthquakes ceased to supply new quantities of it, the southern parts of the atmosphere became negatively electrified with respect to the northern parts. To restore the equilibrium, a vast quantity rushed from the north to the south, visible from the north of Scotland to Paris and farther, in the meteor which appeared on the 18th of August 1783. The immediate consequence of this was, that the atmospheric vapours being left without a proper quantity of electric matter to support them, violent rains took place and continued for some time; a very severe winter succeeded an hot summer, and no remarkable alteration in the weather took place till May.

In most parts of the world, the general state of the weather is determined by their situation with regard to the sea, mountains, &c. In general, mountainous countries are subjected to violent rains, storms of wind, very often thunder and lightning. In some places, particularly the southern part of the continent of America, the weather is almost a continual tempest. The Cape of Good Hope is also remarkable for storms, but chiefly of wind; while Terra del Fuego and the opposite point of the continent is deluged with perpetual rains. The Isthmus of Darien is also remarkable for rainy weather, while in the whole empire of Peru

it scarce ever rains. Persia, Egypt, and some other countries, are likewise destitute of rain, without having the inconvenience of earthquakes to which Peru is subject. The reason of these variations cannot be assigned without a more particular knowledge of the situation of those countries than we can boast of. In general, however, it is known, that high mountains have the property of collecting clouds in their neighbourhood, and consequently of producing rains, thunder, and storms of wind. Where a country is nearly surrounded by a vast extent of sea, it is commonly subject to great rains. Hence the climate of islands is more rainy than of continents; and hence probably the reason of the rains in South America and the Isthmus of Darien, which approach to an insular situation. The great drifels of the air in Peru may be occasioned by the violent determination of the vapours to these parts, which deprive that country of its due proportion: but this can only be hinted as a conjecture, and we have not sufficient data to establish any thing certain.

To conclude this article, we ought now to give an account of those alterations in the air which predict a change of weather, or rather inform us that the weather actually is changing. These, however, are but few, and not always certain. The brute creation are much more sensible of them than we; and give information by various means, according to their peculiar instincts. Those who are much in the open air also will be much better able to perceive these alterations, than such as are not. The barometer is the most certain index we have, and will frequently inform us of a change before the least sign of it can be otherwise perceived. But though we are thus informed that some change is about to take place, we are at a loss to know what it is, and can only guess from the season of the year what kind of weather we may reasonably expect. Thus, in the summer-months, if the wind is easterly, the barometer falls, and the clouds in the west seem stationary, or move a little to the eastward, we may certainly expect thunder at no great distance. If the wind is brisk, and the clouds move before it heavily and sluggishly, we are also to expect thunder, but at a distance. Indeed, we may judge of the approach of thunder-clouds by the time of the day in which they appear. When the sun has reached the meridian, his power of rarefying the air above any particular spot is then greatest. Hence, as this luminary is continually moving to the westward, the increase of the rarefaction towards that quarter must prevent any current of air from blowing from the west, and at the same time solicit a current from the east: but if by some other cause a westerly wind shall prevail, and drive the clouds directly against the easterly one, it is then plain that nothing further can stop their progress; they will be violently electrified, and discharge their contents directly over our heads. Hence the vulgar observation in this country, that if thunder begins at eleven in the forenoon, we will probably have but little; but a great deal, and very near, if it begins at twelve, or between twelve and one.

Another pretty certain indication of an approaching change of weather is a great clearness and transparency in the atmosphere. This is commonly taken notice of when the moon is newly changed. If at that time we see distinctly the part of the moon which is not en-

lightened by the sun's rays, we are pretty certain that rough stormy weather is soon to ensue. In warm climates this transparency is not confined to the atmosphere, but extends even to the waters of the ocean: and when the bottom is visible at a great depth, it is a certain prognostic of an hurricane. This transparency denotes some internal agitation of the electric fluid; for by a certain motion of it even the most solid bodies may be made transparent as glass, (see *ELECTRICITY, Encycl.* n^o 4.); and the agitation becoming more and more violent, at last produces the most terrible commotions in the atmosphere. Something similar may be observed with regard to the transmission of sound; for in such states of the atmosphere sounds are heard much more difficultly and at a greater distance than others; but a sufficient number of observations have not yet been made to determine this matter with any accuracy.

It would be tedious to enter into a detail of all the prognostics which are drawn from the various appearances of the clouds, of halos, parhelia, aurora borealis, &c. Every person expects rain when the sky begins to grow hazy and dull; and halos and parhelia only appear in such cases. As for the aurora borealis, it is often seen for many nights together without any remarkable change in the state of the atmosphere. It is the natural effect of a constant and regular cause, and is probably too high in the atmosphere to produce any remarkable effect; though it has been thought in some cases to be productive of a current of wind from the south-west, for which a probable reason is assigned under the article *AURORA BOREALIS*, n^o ult.

WHEAT-EAR, (*MOTACILLA Oenanthe*), in ornithology, a species omitted to be described under *MOTACILLA*. It is a bird of passage, and begins to visit us about the middle of March, and continues coming till the beginning of May: it has been observed that the females arrive about a fortnight before the males. They frequent warrens, downs, and the edges of hills, especially those that are fenced with stone-walls. They breed in the latter, in old rabbit-burrows, cliffs, and frequently under old timber: their nest is large, made of dried grass, rabbit's down, a few feathers, and horse-hair: and they lay from six to eight eggs, of a light-blue colour.

They grow very fat in autumn, and are esteemed a delicacy. About Eastbourn in Suffex they are taken by the shepherds in great numbers, in snares made of horse hair, placed under a long turf: being very timid birds, the motion of a cloud, or the appearance of a hawk, will drive them for shelter into those traps, and so they are taken. The numbers annually ensnared in that district alone, amount to about 1850 dozen, which sell usually at six-pence per dozen; and what appears very extraordinary, the numbers that return the following year do not appear to be lessened. The reason that such a quantity are taken in the neighbourhood of Eastbourn is, that it abounds with a certain fly which frequents the adjacent hills, for the sake of the wild thyme they are covered with; which is not only a favourite food of that insect, but the plant on which it deposits its eggs.

Wheat-ears are much fatter in a rainy season than in a dry one; for they not only feed on insects but on earth-worms, which come out of the ground in greater numbers in wet weather than in dry.

The head and back of the male are of a light grey, tinged

White,
Whyte.

Whyte.

tinged with red: over each eye is a white line; beneath that is a broad black stroke, passing across each eye to the hind part of the head: the rump and lower half of the tail are white; the upper half black: the under side of the body is white, tinged with yellow; on the neck it inclines to red: the quill-feathers are black, edged with reddish brown. The colours of the female are more dull: it wants that black stroke across the eyes, and the bar of white on the tail is narrower. These birds disappear in September, at least from the northern parts of this kingdom; but in Hampshire many of them continue the whole winter.

WHITE-THROAT, (*MOTACILLA Sylva*), in ornithology, a species omitted under the article **MOTACILLA**. It frequents our gardens in the summer-time; in the winter it leaves us. It builds in low bushes near the ground, making its nest externally of the tender stalks of herbs and dry straw; the middle part of fine bents and soft grass, the inside of hair. It lays five eggs of a whitish green colour, sprinkled with black spots. Its note is continually repeated, and often attended with odd ejaculations of the wings: is harsh and displeasing: is a shy and wild bird, avoiding the haunt of man; seems of a pugnacious disposition, singing with an erected crest, and in attitudes of defiance.

The head of this bird is of a brownish ash-colour, the throat white: the breast and belly white, tinged with red (in the female wholly white): the back inclines to red: the lesser coverts of the wings are of a pale brown; the greater dusky, edged with tawny brown; the quill-feathers dusky, edged with reddish brown; the tail the same, except the upper part of the interior side and whole exterior side of the outmost feather, which are white; the legs are of a yellowish brown.

WHYTE (Dr Robert), an eminent physician, born at Edinburgh on the 6th September 1714, was the son of Robert Whyte, Esq; of Kennoway, advocate. This gentleman died six months before the birth of our author, who had also the misfortune to be deprived of his mother before he had attained the seventh year of his age. After receiving the first rudiments of school-education, he was sent to the university of St Andrews; and after the usual course of instruction there, in classical, philosophical, and mathematical learning, he came to Edinburgh, where he entered upon the study of medicine, under those eminent medical teachers, Munro, Rutherford, Sinclair, Plummer, Allron, and Innes. After learning what was to be acquired at this university, in the prosecution of his studies he visited foreign countries; and after attending the most eminent teachers at London, Paris, and Leyden, he had the degree of Doctor of Medicine conferred upon him by the university of Rheims in 1736, being then in the 22d year of his age.

Upon his return to his native country, he had the same honour also conferred upon him by the university of St Andrews; where he had before obtained, with applause, the degree of Master of Arts.

Not long afterwards, in the year 1737, he was admitted a Licentiate of Medicine by the Royal College of Physicians of Edinburgh; and the year following he was raised to the rank of a Fellow of the College. From the time of his admission as a licentiate, he entered upon the practice of medicine at Edinburgh; and the reputation which he acquired for medical learn-

ing, pointed him out as a fit successor for the first vacant chair in the university. Accordingly, when Dr St-Clair, whose eminent medical abilities, and persuasive powers of oratory, had contributed not a little to the rapid advancement of the medical school of Edinburgh, found that those conspicuous talents which he possessed could no longer be exerted in the manner which they once had been when he enjoyed bodily vigour unimpaired by age, and powers of mind unclouded by disease, he resigned his academical appointments in favour of Dr Whyte.

This admission into the college took place on the 20th of June 1746; and he began his first course of the institutions of medicine at the commencement of the next winter-session. The abilities which he displayed from his academical chair, in no particular disappointed the expectations which had been formed of his lectures. The Latin tongue was the language of the university of Edinburgh; and he both spoke and wrote in Latin with singular propriety, elegance, and perspicuity. At that time the fystem and sentiments of Dr Boerhaave, which, notwithstanding their errors, much challenge the admiration of later ages, were very generally received by the most intelligent physicians in Britain. Dr Whyte had no such idle ardour for novelties as to throw them entirely aside because he could not follow them in every particular. The institutions of Dr Boerhaave, therefore, furnished him with a text for his lectures; and he was no less successful in explaining, illustrating, and establishing the sentiments of the author, when he could freely adopt them, than in refuting them by clear, connected, and decisive arguments, when he had occasion to differ from him. The opinions which he himself proposed, were delivered and enforced with such acuteness of invention, such display of facts and force of argument, as could rarely fail to gain universal assent from his numerous auditors; but free from that self-sufficiency which is ever the offspring of ignorance and conceit, he delivered his conclusions with becoming modesty and diffidence.

From the time that he first entered upon an academical appointment, till the year 1756, his prælections were confined to the institutions of medicine alone. But at that period his learned colleague Dr Rutherford, who then filled the practical chair, who had already taught medicine at Edinburgh with universal applause for more than thirty years, and who had been the first to begin the institution of clinical lectures at the Royal Infirmary, found it necessary to retire from the fatiguing duties of an office to which the progress of age rendered him unequal. On this crisis Dr Whyte, Dr Munro, sen. and Dr Cullen, each agreed to take a share in an appointment in which their united exertions promised the highest advantages to the university. By this arrangement, students who had an opportunity of daily witnessing the practice of three such teachers, and of hearing the grounds of that practice explained, could not fail to derive the most solid advantages.

In these two departments, the institutions of medicine in the university, and the clinical lectures in the Royal Infirmary, Dr Whyte's academical labours were attended with the most beneficial consequences both to the students and to the university. But not long after the period we have last mentioned, his lectures on the former of these subjects underwent a very considerable change. About this time the illustrious Gaubius, who had succeeded to the chair of Boerhaave, favoured the

the world with his *Institutiones Pathologiæ*. This branch of medicine had indeed a place in the text which Dr Whyte formerly followed; but, without detracting from the character of Dr Boerhaave, it may justly be said, that the attention he had bestowed upon it was not equal to its importance. Dr Whyte was sensible of the improved state in which pathology now appeared in the writings of Boerhaave's successor; and he made no delay in availing himself of the advantages which were then afforded.

In the year 1762, his pathological lectures were entirely new modelled. Following the publication of Gaubius as a text, he delivered a comment, which was read by every intelligent student with the most unfeigned satisfaction. In these lectures he collected and condensed the fruits of accurate observation and long experience. Enriched by all the opportunities of information which he had enjoyed, and by all the discernment which he was capable of exerting, they were justly considered as his most finished production.

For a period of more than twenty years, during which he was justly held in the highest esteem as a lecturer at Edinburgh, it may readily be supposed that the extent of his practice corresponded to his reputation. In fact, he received both the first emoluments, and the highest honours, which could here be obtained. With extensive practice in Edinburgh, he had numerous consultations from other places. His opinion on medical subjects was daily requested by his most eminent contemporaries in every part of Britain. Foreigners of the first distinction, and celebrated physicians in the most remote parts of the British empire, courted an intercourse with him by letter. Besides private testimonies of esteem, many public marks of honour were conferred upon him both at home and abroad. In 1752, he was elected a fellow of the Royal Society of London; in 1761, he was appointed first physician to the king in Scotland; and in 1764, he was chosen president of the Royal College of Physicians at Edinburgh.

But the fame which Dr Whyte acquired as a practitioner and teacher of medicine, were not a little increased by the information which he communicated to the medical world in different publications. His celebrity as an author was still more extensive than his reputation as a professor.

His first publication, an *Essay on the Vital and other Involuntary Motions of Animals*, although it had been begun soon after he had finished his academical course of medical education, did not come from the press till 1751; a period of fifteen years from the time that he had finished his academical course, and obtained a degree in medicine; but the delay of this publication was fully compensated by the matter which it contained, and the improved form under which it appeared.

The next subject which employed the pen of Dr Whyte was one of a nature more immediately practical. His *Essay on the Virtues of Lime-water and Soap in the Cure of the Stone*, first made its appearance in a separate volume in 1752. Part of this second work had appeared several years before in the *Edinburgh Medical Essays*: but it was now presented to the world as a distinct publication, with many improvements and additions.

His third work, intitled *Physiological Essays*, was

first published in the year 1755. This treatise consisted of two parts; 1st, An Inquiry into the Causes which promote the Circulation of the Fluids in the very small Vessels of Animals; and 2dly, Observations on the sensibility and irritability of the Parts of Men and other Animals, occasioned by Dr Haller's treatise on that subject. The former of these may be considered as an extension and farther illustration of the sentiments which he had already delivered in his *Essay on the Vital Motions*, while the latter was on a subject of a controversial nature. In both he displayed that acuteness of genius, and strength of judgment, which acquired in his former writings.

From the time at which his *Physiological Essays* were published, several years were probably employed by our author in preparing for the press a larger and perhaps a more important work than any yet mentioned, his *Observations on the Nature, Causes, and Cure of those Disorders which are commonly called nervous, hypochondriac, and hysterical*. This elaborate and useful work was published in the year 1764.

The last of Dr Whyte's writings is intitled, *Observations on the Dropsy in the Brain*. This treatise did not appear till two years after his death; when all his other works were collected and published in one quarto volume, under the direction of his son and of his intimate friend the late Sir John Pringle.

Besides these five works, he wrote many other papers, which appeared in different periodical publications; particularly in the *Philosophical Transactions*, the *Medical Essays*, the *Medical Observations*, and the *Philosophical and Literary Essays*.

At an early period of life, soon after he had settled as a medical practitioner in Edinburgh, he entered into the married state. His first wife was Miss Robertson, sister to General Robertson late governor of New York. By her he had two children; both of whom died in early infancy, and their mother did not long survive them. A few years after the death of his first wife, he married as a second wife Miss Balfour, sister to the present James Balfour, Esq; of Pilrig. By her he had fourteen children: but in these also he was in some respects unfortunate; for six of them only survived him, three sons and three daughters, and of the former two are since dead. Although the feeling heart of Dr Whyte, amidst the distresses of his family, must have often suffered that uneasiness and anxiety which in such circumstances is the unavoidable consequence of parental affection and conjugal love; yet he enjoyed a large share of matrimonial felicity. But his course of happiness was terminated by the death of his wife, which happened in the year 1764: and it is not improbable that this event had some share in hastening his own death; for in the beginning of the year 1765 his health was so far impaired, that he became incapable of his former exertions. A tedious complication of chronic ailments, which chiefly appeared under the form of diabetes, was not to be resisted by all the medical skill which Edinburgh could afford; and at length terminated in death, on the 15th of April 1766, in the 52d year of his age.

WILDERNESS, (*Encycl.*) Wilderesses, says Mr Miller, should always be proportioned to the extent of the gardens in which they are made; for it is very ridiculous to see a large wilderness planted with tall trees in a small

Whyte,
Wilderness.

Wilderness. small spot of ground; and, on the other hand, nothing can be more absurd than to see little paucity squares, or quarters of wilderness-work, in a magnificent large garden. As to the situation of wildernesses, they should never be placed too near the habitation, nor so as to obstruct any distant prospect of the country, there being nothing so agreeable as an unconfined prospect: but where, from the situation of the place, the sight is confined within the limits of the garden, nothing can be so agreeably terminate the prospect as a beautiful scene of the various kinds of trees judiciously planted; and if it is so contrived that the termination is planted circularly, with the concave towards the sight, it will have a much better effect than if it end in straight lines or angles. The plants should always be adapted to the size of the plantation; for it is very absurd for tall trees to be planted in the small squares of a little garden; and in large designs small shrubs will have a mean appearance. It should also be observed never to plant evergreens amongst deciduous trees; but always to place the evergreens in a wilderness in a separate part by themselves, and that chiefly in sight.

As to the walks, those that have the appearance of meanders, where the eye cannot discover more than twenty or thirty yards in length, are generally preferable to all others, and these should now and then lead into an open circular piece of grass; in the centre of which may be placed either an obelisk, statue, or fountain; and if in the middle of the wilderness there be contrived a large opening, in the centre of which may be erected a dome or banqueting-house, surrounded with a green plot of grass, it will be a considerable addition to the beauty of the whole. From the sides of the walks and openings, the trees should rise gradually one above another to the middle of the quarters, where should always be planted the largest growing trees, so that the heads of all the trees may appear to view, while their stems will be hid from the sight. Thus, in those parts which are planted with deciduous trees, roses, honeysuckles, spiræa frutex, and other kinds of low-flowering shrubs, may be planted next the walks and openings; and at their feet, near the sides of the walks, may be planted primroses, violets, daffodils, &c. not in a straight line, but so as to appear accidental, as in a natural wood. Behind the first row of shrubs should be planted syringas, althæa frutex, mezerions, and other flowering-shrubs of a middle growth; and these may be backed with many other sorts of trees, rising gradually to the middle of the quarters.

The part planted with evergreens may be disposed in the following manner, viz. in the first line next the great walks may be placed the laurus tinus, boxes, spurge-laurel, juniper, savin, and other dwarf evergreens. Behind these may be placed laurels, hollies, arbutuses, and other evergreens of a larger growth. Next to these may be planted alaternuses, phyllireas, yews, cypresses, Virginian cedars, and other trees of the same growth; behind these may be planted Norway and silver firs, the true pine, and other sorts of the fir-growth; and in the middle should be planted Scotch pines, pinasters, and other of the larger growing evergreens; which will afford a most delightful prospect if the different shades of the greens are curiously intermixed.

But beside the grand walks and openings (which should always be laid with turf, and kept well mowed), there should be some smaller serpentine walks

through the middle of the quarters, where persons may retire for privacy; and by the sides of these private walks may also be scattered some wood-flowers and plants; which, if artfully planted, will have a very good effect.

In the general design for these wildernesses, there should not be a studied and stiff correspondency between the several parts; for the greater diversity there is in the distribution of these, the more pleasure they will afford.

WINTER'S BARK. See the two following articles.

WINTERANIA, in botany, a genus of the monogynia order, belonging to the dodecandria class of plants; for the characters of which, see the *BOTANY Table*. There is but one species, the canella; see Plate CCLXXXVI. It grows usually about 20 feet high, and eight or ten inches in thickness, in the thick woods of most of the Bahama islands. The leaves are narrow at the stalk, growing wider at their ends, which are broad and rounding, having a middle rib only; they are very smooth, and of a light shining green. In May and June the flowers, which are pentapetalous, come forth in clusters at the ends of the branches: they are red, and very fragrant, and are succeeded by round berries, of the size of large peas, green, and when ripe (which is in February) purple, containing three shining black seeds, flat on one side, otherwise not unlike in shape to a kidney-bean: these seeds in the berry are enveloped in a slimy mucilage. The whole plant is very aromatic, the bark particularly, being more used in distilling, and in greater esteem, in the more northern parts of the world than in England. This bark is that which is commonly known in the shops by the name of *Winter's bark*; tho' truly not the right, as Sir Hans Sloane has judiciously informed us. See the following article.

WINTERANIA Aromatica, the tree which produces the *Winter's bark*. Formerly this tree was utterly unknown to the Europeans till the return of Captain John Winter, who, in the year 1577, sailed with Sir Francis Drake, as commander of a ship called the *Elizabeth*, destined for the South Seas; but immediately after they had gone through the Straights of Magellan, Captain Winter, on the 8th of October 1578, was obliged by stress of weather to part company, and to go back again into the Straights, from whence he returned into England in June 1579, and brought with him several pieces of this aromatic bark; which Clusius, in his *Exot.* p. 75. calls after him *Cortex Winteranus*, or *Winter's bark*.

Several authors have mentioned it since in their botanical works; but all they have said has been copied from Clusius, *e. g.* Dalechamp hist. p. 1818. Parkinson Theat. p. 1652. *Baubin Pin.* 461. *Jonglson Dendr.* p. 232.

No more was heard of this bark till the Dutch fleet under admiral Van Nort returned from the Straights of Magellan in the year 1600. The author of their voyage calls this tree "Lauro similis arbor licet prociore, cortice piperis modo acri et mordenti." *De Bry. Ind. Occid.* vol. 9. p. 18.

Afterwards all the navigators who passed through the Straights of Magellan took notice of the tree on account of the usefulness of its bark; but none furnished any description that could make it botanically known, before Mr George Handasyd came from the Straights

Streights of Magellan, 1691, and brought with him some dried specimens, which he gave to Sir Hans Sloane, and are now preserved in the British Museum, Hort. Sicc. 8. fo. 100. 130. 148. 332. fo. 46. From these specimens, and the account Mr Handasyd gave of this tree, Sir Hans Sloane drew up a history, and gave a figure in the Philosophical Transactions, 1693. n^o 204. p. 922. t. 1. "Periclymenum rectum, foliis laurinis, cortice acri aromatico."

Still the systematical botanists could not give it a place in their catalogues, being unacquainted with its flowers and fruit.

Pomet, in his Mat. Med. p. 130. imagined our Winter's bark to be the same with the canella cinnamomea, Brown Hist. Jam. p. 275, fo. 3. Catesby Carol. vol. 2. p. 50. which grows in the West Indies, between the tropics, and is called by the drug-gifts *canella alba*. This error has been followed by most of the modern writers, and the two trees proposed under the same name, viz. *Winterania Canella*, Lin. Sp. Pl. 638.

At length Dr Fothergill procured figures to be taken from the specimens brought by Captain Wallis from the Streights of Magellan, and prevailed with Dr Solander to give such a history and description of the tree as might enable botanists to place it in its proper rank. These were communicated to the London Medical Society, and published in the fifth volume of their *Observations and Inquiries*.

From the observations made by Sir Joseph Banks and Dr Solander during their stay in Terra del Fuego, it seems as if the trees in the Streights of Magellan, near the sea coast, are stunted, perhaps from the high winds, and have smaller leaves than those upon Terra del Fuego, where again the flowers were not so much expanded as in the Streights of Magellan. This last difference may be occasioned by the season, as the flowers on Terra del Fuego were seen in the month of January, and in the Streights of Magellan in the month of March.

The Winter's-bark tree, *Winterania aromatica*, is one of the largest forest-trees upon Terra del Fuego; it often rises to the height of 50 feet. Its outward bark is on the trunk grey and very little wrinkled, on the branches quite smooth and green.

The branches do not spread horizontally, but are bent upwards, and form an elegant head of an oval shape.

The leaves come out, without order, of an oval elliptic shape, quite entire, obtuse, flat, smooth, shining, of a thick leathery substance, evergreen, on the upper side of a lively deep green colour, and of a pale bluish colour underneath, without any nerves, and their veins scarcely visible; they are somewhat narrower near the footstalks, and there their margins are bent downwards.

In general, the leaves are from three to four inches long, and between one and two broad; they have very short footstalks, seldom half an inch long, which are smooth, concave on the upper side, and convex underneath. From the scars of the old footstalks the branches are often tuberculated.

The peduncles, or footstalks for the flowers, come out of the *axillæ foliorum*, near the extremity of the branches; they are flat, of a pale colour, twice or three times shorter than the leaves; now and then they

support only one flower, but are oftener near the top divided into three short branches, each with one flower.

The bractææ are oblong, pointed, concave, entire, thick, whitish, and situated one at the basis of each peduncle.

Calix, or flower-cup, it has none; but in its place the flower is surrounded with a spathaceous gem, of a thick leathery substance, green, but reddish on the side which has faced the sun: before this gem bursts, it is of a round form, and its size is that of a small pea. It bursts commonly so, that one side is higher than the other, and the segments are pointed.

The corolla consists always of seven petals, which are oval, obtuse, concave, erect, white, have small veins, and are of an unequal size, the largest scarcely four lines long; they very soon fade, and drop off almost as soon as the gem bursts.

The filaments are from 15 to 30, and are placed on the flat end side of the receptacle; they are much shorter than the petals, and gradually decrease in length towards the sides.

The antheræ are large, oval, longitudinally divided into two, or as if each was made up of two oblong antheras.

The germina are from three to six, placed above the receptacle, turbinate, or of the shape of an inverted fig, flat on the inside, and somewhat higher than the stamina; they have no styles, but terminate in a stigma, which is divided into two or three small lobes.

Dr Solander never saw the fruit in its perfect ripe state; but could conclude from the unripe ones which he saw in abundance, that each germen becomes a separate seed-vessel, of a thick fleshy substance, and unilocular; and in each the rudiments of three, four, or five seeds were plainly discernible. See Plate CCCXXIII. where n^o 1. represents the spathaceous gem, after it is burst open. 2. The same. 3. The same (a) with the corolla (b) remaining within it. 4. One of the petals spread out. 5. The stamina (a) and the pistilla (b) after the gem and the corolla are taken away. 6. The outside of an anthera (a) with its filament (b). 7. The inside of the same. 8. The germina (a) situated on the centre of the receptacle, after the stamina have been removed; the lobated stigma (b). 9. The convex or outermost side of a germen (a) with its stigma (b). 10. The inside of the same. 11. A germen cut open longitudinally, so as to show the rudiments of the seeds. 12. A germen cut through transversely.

The weather is much more severe in the climate where these trees are natives, than in Britain; where, therefore, it is thought they would thrive very well.

The bark of the *Winterania*, or Winter's cinnamon, brought over by the Dolphin, in respect to figure, exactly resembles that which was delineated by Clusius. The pieces are about three or four inches square, of different degrees of thickness, from a quarter to three quarters of an inch. It is of a dark brown cinnamon colour; an aromatic smell, if rubbed; and of a pungent, hot, spicy taste, which is lasting on the palate, though imparted slowly. It has the name of Winter's *Cinnamon*, from a faint resemblance in colour and flavour to that grateful aromatic, though differing from it greatly in every other respect. This bark is only brought to us from the Streights of Magellan, and is the produce of the tree above described; much celebrated as an anti-

scorbutic by the first discoverers, but unknown in the practice of physick, no quantity, except as a curiosity, having been brought to Europe till the return of the ships sent out on the expeditions to the South Seas.

The bark which was substituted in the room of this is the canella alba of the shops, the bark of a very different tree, and brought from a different part of the world, disagreeing with the former in almost every particular. It is of a light ash or grey colour; in thickness it seldom exceeds two-eighths of an inch. The pieces are of different lengths and irregular shapes, and for the most part are taken from trees of small size: its taste is aromatic, and has more of the clove than the cinnamon. It yields an essential oil by distillation, and is brought to us chiefly from Jamaica, though it is found in some other of the West-India islands. There are a few plants of it in the stoves of some curious botanists in England, particularly in that belonging to John Blackburne, Esq; at Oxford, Lancashire.

Sir Hans Sloane gives a figure of it in his History of Jamaica; from which it evidently appears to be a different genus from the Winterania aromatica.

For want of the knowledge of these circumstances, and an opportunity of comparing the genuine Winter's bark with the canella alba, some of the most respectable writers on the materia medica have scarcely been able to avoid confusion in treating this subject; which it is hoped for the future will be avoided, and the distinction between them sufficiently established.

From several experiments made by Dr Morris, the cortex magellanica appears to be an astrigent of a particular kind, and therefore likely to be of use in several manufactures. Water is the proper solvent of this bark; though the saline, gummy, and resinous parts are so blended in it, as in saffron and some other vegetables, that it parts with them readily in proof and rectified spirits of wine, though not in so great a quantity.

The infusion and decoction of this bark were of so grateful an aromatic bitter taste, that it seems likely to be a pleasant vehicle for some of the nauseous drugs. With this view, on substituting the powder of this bark for the cardamom seeds in making the infusion of fenna, as directed in the London Dispensatory, the nauseous smell and taste of that excellent purgative was so effectually covered, as to be scarcely distinguished by the nicest palate. Tincture of rhubarb also prepared with this bark instead of cardamoms seemed far less disagreeable.

It must not be concealed, that the canella alba from Jamaica, which is generally sold for the Winter's bark in the shops, was found to have the last mentioned property, though not in so high a degree.

WOOD, (*Encycl.*) The art of moulding wood is mentioned by Mr Boyle as a desideratum in the art of carving. He says, he had been credibly informed of its having been practised at the Hague; and suspects that it might have been performed by some menstruum that softens the wood, and afterwards allows it to harden again, in the manner that tortoise-shell is moulded; or, perhaps, by reducing the wood into a powder, and then uniting it into a mass with strong but thin glue. And he adds, that having mixed saw-dust with a fine glue made of isinglass, slightly straining out

what was superfluous through a piece of linen, the remainder, formed into a ball and dried, became so hard as to rebound when thrown against the floor.

The people who work much in wood, and that about small works, find a very surprising difference in it, according to the different seasons at which the tree was cut down; and that not regularly the same in regard to all species, but different in regard to each. The button-mould makers find that the wood of the pear-tree cut in summer works toughest; holly, on the contrary, works toughest when cut in winter; box is mellowest when it has been cut in summer, but hardest when cut about Easter; hawthorn works mellow when cut about October; and the service is always tough if cut in summer.

Woods are distinguished into divers kinds, with regard to their nature, properties, virtues, and uses. Of wood, considered according to its qualities, whether useful, curious, medicinal, &c. the principal is called *timber*, used in building houses, laying floors, roofs, machines, &c.

Woods valued on account of their curiosity, are cedar, ebony, box, calambo, &c. which by reason of their extraordinary hardness, agreeable smell, or beautiful polish, are made into tables, combs, beads, &c.

The medicinal woods are guaiacum, aloes, sassafras, nephriticum, fantal, saraparilla, apalanthum, &c.

Woods used in dyeing are brazil-wood, Campechy-wood, &c.

Fossile Wood. Fossile wood, or whole trees, or parts of them, are very frequently found buried in the earth, and that in different strata; sometimes in stone, but more usually in earth; and sometimes in small pieces loose among gravel. These, according to the time they have lain in the earth, or the matter they have lain among and in the way of, are found differently altered from their original state; some of them having suffered very little change; and others being so highly impregnated with crystalline, sparry, pyritical, or other extraneous matter, as to appear mere masses of stone, or lumps of the common matter of the pyrites, &c. of the dimensions, and, more or less, of the internal figure of the vegetable bodies into the pores of which they have made their way.

The fossile wood which we find at this day, are, according to these differences, arranged by Dr Hill into three kinds; 1. The less altered: 2. The pyritical: and, 3. The petrified.

Of the trees, or parts of them, less altered from their original state, the greatest store is found in digging to small depths in bogs, and among what is called *peat* or *turf earth*, a substance used in many parts of the kingdom for fuel. In digging among this, usually very near the surface, they find immense quantities of vegetable matter buried, and that of various kinds: in some places there are whole trees scarce altered, except in colour; the oaks in particular being usually turned to a jetty black; the pines and firs, which are also very frequent, are less altered, and are as inflammable as ever, and often contain between the bark and wood a black resin. Large parts of trees have also been not unfrequently met with unaltered in beds of another kind, and at much greater depths, as in the strata of clay and loam, among gravel, and sometimes even in solid stone.

1897
1898

[Faint, illegible text at the bottom of the page, possibly bleed-through.]

Beside these harder parts of trees, there are frequently found also in the peat-earth vast quantities of the leaves and fruit and catkins of the hazel and the like trees: these are usually intermixed among the sedge and roots of grass, and are scarce at all altered from their usual texture. The most common of these are hazel nuts; but there are frequently found also the twigs and leaves of the white poplar; and a little deeper usually there lies a cracked and shattered wood, the crevices of which are full of a bituminous black matter; and among these the stones of plums and other stone-fruits are sometimes found, but that more rarely.

It is idle to imagine, that these have been thus buried either at the creation, or, as many are fond of believing, at the universal deluge. At the first of these times the strata must have been formed before the trees were yet in being; and the peat-wood is so far from being of antediluvian date, that much of it is well known to have been growing within these 300 years in the very places where it is now found buried.

In this state that is little altered from their original condition, it is that the fruits and larger parts of trees are usually found: what we find of them more altered, are sometimes large and long, sometimes smaller and shorter branches of trees, sometimes small fragments of branches, and more frequently small shapeless pieces of wood. The larger and longer branches are usually found bedded in the strata of stone, and are more or less altered into the nature of the stratum they lie in. The shorter and smaller branches are found in vast variety in the strata of blue clay used for making tiles in the neighbourhood of London. These are prodigiously plentiful in all the clay-pits of this kind, and usually carry the whole external resemblance of what they once were, but nothing of the inner structure; their pores being wholly filled, and undistinguishably closed, by the matter of the common vitriolic pyrites, so as to appear mere simple masses of that matter. These fall to pieces on being long exposed to moisture; and are so pregnant in vitriol that they are what is principally used for making the green vitriol or copperas at Deptford and other places.

The irregular masses or fragments of wood are prin-

cipally of oak, and are most usually found among gravel; though sometimes in other strata. These are variously altered by the insinuation of crystalline and stony particles; and make a very beautiful figure when cut and polished, as they usually keep the regular grain of the wood, and show exactly the several circles which mark the different years growth. These, according to the different matter which has filled their pores, assume various colours, and the appearance of the various fossils that have impregnated them; some are perfectly white, and but moderately hard; others of a brownish black, or perfectly black, and much harder; others of a reddish black, others yellowish, and others greyish, and some of a ferruginous colour. They are of different weights also and hardesses, according to the nature and quantity of the stony particles they contain: of these some pieces have been found with every pore filled with pure pellucid crystal; and others in large masses, part of which is wholly petrified and seems mere stone, while the rest is crumbly and is unaltered wood. That this alteration is made in wood, even at this time, is also abundantly proved by the instances of wood being put into the hollows of mines, as props and supports to the roofs, which is found after a number of years as truly petrified as that which is dug up from the natural strata of the earth. In the pieces of petrified wood found in Germany, there are frequently veins of spar or of pure crystal, sometimes of earthy substances, and often of the matter of the common pebbles: these fragments of wood sometimes have the appearance of parts of the branches of trees in their natural state, but more frequently they resemble pieces of broken boards; these are usually capable of a high and elegant polish.

Many substances, it is certain, have been preserved in the cabinets of collectors, under the title of *petrified wood*, which have very little right to that name. But where the whole outer figure of the wood, the exact lineaments of the bark, or the fibrous and fistular texture of the stræ, and the vestiges of the utriculi and tracheæ or air-vessels, are yet remaining, and the several circles yet visible which denoted the several years growth of the tree, none can deny these substances to be real fossil wood.

LIST of the principal AUTHORS used in compiling the preceding Work.
